Bohnalite is the favorite light alloy of the aircraft industry because it conforms most admirably to aeronautical requirements.

Technical control and special heat treatments, applied to this series of light alloys, have developed physical properties of the utmost importance to safe aircraft construction.

What are your casting problems? Undoubtedly Bohnalite castings can be of assistance.

KINNER

Low starting effect

High speed—high temperature operation

The New Mobiloil Aero "W"

Special "double-range" oil for temperatures below 32° F

Two important qualities an oil must have for correct winter lubrication of aircraft engines:

1. Perfect fluidity at winter temperatures—insures oil flows at the moment of "crank."
2. Full body at winter operating temperatures—rich lubricating protection under heat and load conditions.

The New Mobiloil Aero "W" is unique among winter aviation oils. Its distinctive "double-range" character assures easy starting and immediate oil circulation in zero weather, plus rich, full-bodied lubrication at all winter operating temperatures.

This new winter addition to the "Double-Range" line of Mobiloil Aero Oils is now on sale at established airports throughout the world.

PRECISION AIRCRAFT ENGINE PARTS

Ex-Cell-O is Prepared to Furnish Gears of Superior Accuracy

The completion of the new Ex-Cell-O gear plant embracing the most modern and efficient of gear machinery and gear inspection equipment now brings "Ex-Cell-O precision" to this important branch of aircraft engine manufacture!

Due to their extreme lightness and the excessive loads which they must carry, aircraft gears require the utmost accuracy in heat-treating and fabrication—a degree of accuracy which Ex-Cell-O, by reason of experience and equipment—is prepared to furnish.

All Ex-Cell-O aircraft engine parts are made to engine manufacturer's specifications. Send complete specifications and blue prints when requesting quotations.

Ex-Cell-O also manufactures Ex-Cell-O Drill Jig Bushings, the celebrated Ex-Cell-O Grinding Spindles and Diesel engine fuel pump parts.

CONSIDER the negative sales effect of a rough landing! When your dealer finds a prospect in your shop there is one moment at the point of landing when he is anxious to see things—smoothness! For that reason, when demonstrating, the pilot is careful to set it down easy, sometimes a little fast, if necessary...he knows! But if the plane comes in a bit too fast or a bit too slow, there is a rough rebounding landing. Not so with Gruss. Pilots have learned that Gruss Stents absorb the landing impact without rebound. A Gruss equipped plane is never jolted in. When it settles down to land, fast or slow,

it gives no rebound. If there you investigated the new Gruss Shock Unit, efficiently streamlined in our factory and shipped to you complete with fittings ready for immediate installation in your plane! You know value resistance and to secure complete owner satisfaction through smooth landings, equip your ship with Gruss. Complete information.

Record Flight Service

IN every outstanding American aeronautical achievement since 1921, Thompson Valves have contributed importantly to motor efficiency and dependability.

Unusual resistance to burning, blistering, warping, pitting and carbon accumulation, have established them as unquestioned leaders in the field. Today, they are installed as original equipment in 95 per cent of all American-built aero motors.

**Thompson
Valves**

OF
**EXTRA
MILEAGE**

that's what you get with every filling of

PENNZOIL

"THE BEST MOTOR OIL IN THE WORLD"

There is enough reserve mileage in every filling of Pennzoil to take you more than half way across the continent. Here are the figures:

Ordinary oils must be drained at 15 hours. Pennzoil may be used from 30 to 40 hours. In other words, Pennzoil gives you at least 15 extra hours with every filling.

What does this reserve mileage mean? In the first place, it means reserve safety—it guarantees you extra endurance in every emergency.

In the second place, it means reserve power. The reason—Pennzoil resists continued heat and friction—you'll never know what giving her the gun means until you give your motor Pennzoil.

Third, this reserve mileage stands for economy—not only in the cost of the oil itself, but as insurance against high repair costs and worn-out motors.

No wonder America's greatest passenger lines specify Pennzoil for

every plane. No wonder that operators who look at lubrication from a business standpoint choose Pennzoil. Pennzoil is made from 100% pure Pennsylvania crude—and nothing else. It is always uniform in quality because it is refined only by the famous Pennzoil process in the refineries of the Pennzoil Company—largest organization in the world operating exclusively on Pennsylvania crude.

Use Pennzoil—and you'll never worry about lubrication trouble again!

THE PENNZOIL COMPANY, Oil City, Pa.

PENNZOIL

HIGHEST QUALITY PENNSYLVANIA OIL

SUSTAINED HIGH COMPRESSION at SUSTAINED HIGH SPEED

is achieved with
Pedrick
HEAT-SHAPED
PISTON RINGS

AFTER the most grueling tests, PEDRICK Piston Rings are today being specified by many of the nation's aeronautical engineers and have been adopted as Standard Equipment by leading engine builders. From the beginning they have been used by the Air Mail Division of the United States Post Office Department, and are now used by many of the private contractors who have taken over this service.

PEDRICK Heat Shaped Rings are "Tensed"—and they "stay tensed" because they are set to tension by heat. They do not warp—lose tension or wear irregularly. That is why they assure "High Compression" at sustained "High Speeds."

Write for the name of the nearest Distributor carrying a complete stock of PEDRICK Oil Control and compression rings.

Wilkening Manufacturing Co.
Philadelphia

The **ROCKER BOX** indicates **ADVANCED** design

The compensating rocker box used on the Axelson B type Motor maintains uniform valve clearance hot or cold. The valves are set cold and cylinder growth, which occurs when the motor warms up, is counteracted by the hinged and spring steel supported rocker box. The dual ball bearing rocker arms have positive Zerk lubrication.

Our new Catalog, describing the Axelson Type B 150 h.p. Engine gives interesting information on the most advanced engine design.

Cutting Production Costs for the Entire Industry

In the aircraft industry, as in the automobile industry, mass production is the solution for high manufacturing costs. Every aircraft manufacturer who is alert to the present market conditions, also realizes that production costs and subsequent selling prices on ground and aircraft are responsible for the limited general market for his product. The Aircraft Products Corporation, secured for aircraft line mass production on standard aircraft parts in saving production costs for America's leading aircraft manufacturers. Our manufacturing facilities - our low selling prices - are a directly of products, and the volume of our business,

provide a greater degree of economy and lower workmanship at a lower price per unit. Time, too, can be saved through the economy of this mass production. Save time - our engineering staff will gladly cooperate with you in problems of design or adaptation.

UNIFORM QUALITY FEATURES

CO-VE-CO PLYWOODS

EVERY square inch of CO-VE-CO Aircraft Plywood is uniform in quality, in cellular structure and in composite strength! It is manufactured, as well, to exact uniform thickness... CO-VE-CO uniformity is achieved by an exclusive method of manufacture that preservative-grade veneer from logs in their natural state as they come from the forest. Under the CO-VE-CO process steaming or cooking to soften woods for peeling is unnecessary. Every layer is instant; some are laminated, rolls are not ruptured. Every square inch of CO-VE-CO veneer retains the mighty strength en-

dowed by nature through centuries of growth... Secure this uniformity for your 1939 production! CO-VE-CO Aircraft Plywoods, manufactured from Port Orford Cedar or Selected Sitka Spruce bring added structural strength to your aircraft. Sheets of standard sizes and thicknesses are stocked for immediate delivery. Or if you prefer, communicate with our Sales Representatives for information on how CO-VE-CO Aircraft Plywoods may be manufactured to your own specifications for sheet sizes and accurate thicknesses.

POINTS OF SUPERIORITY

- 1 THRUST BEARING**—positively clamped between steel surfaces insuring permanent adjustment of crank shaft and plug.
- 2 MAIN BEARINGS**—are ball bearings tightly clamped against crank cheeks eliminating overhung crank loads. Bearings are supported in crank case by line ground steel sleeves.
- 3 COUNTER WEIGHTS**—stroke fitted and cross locked to crank cheeks in a manner which effectively and safely absorbs torque impulses and centrifugal forces.
- 4 SPARK PLUGS** set in bronze inserts and so placed as to insure rapid and complete combustion of the gases and eliminate spark plug fouling.
- 5 ROCKER ARM ROLLER** eliminates slide thrust when transmitting motion to valves, insures long life to valve guides.
- 6 ROCKER ARM**, ball bearing mounted. Bearings sealed to retain lubricant and prevent corrosion.
- 7 PUSH ROD SOCKET** in rear end of rocker arm receives lubrication automatically when lubricating rocker arm bearings.
- 8 PUSH RODS**—coated by teflon preventing complete protection from dust and insuring adequate quantities of lubricant or pushed ballroads.
- 9 CAM FOLLOWER GUIDES**—supported throughout entire length by being set in ground bases, absolutely preventing destructive slide motion.
- 10 CAM RING**, Alloy steel with integral gear rotating slowly at 1/10th engine speed on extra large ballroad bearing. Adequately lubricated insuring permanent adjustment for life of engine.
- 11 REPLACABLE BRONZE BUSHINGS** are provided for every revolving shaft not supported by a ball bearing. All pressure lubricated. This makes for ease of replacement and prevents any damage to the expensive main castings.
- 12 MAGNETO DRIVE**—Ball bearing mounted and fitted with shock-absorbing flexible drive, provided with Vernier adjustment, insuring perfect alignment and close synchronization of magnetos.
- 13 OIL PRESSURE PASSAGES**—are all lateral, contained within engine parts, eliminating exterior pressure lines.
- 14 OIL PUMP**—Pressure and Suction Pumps twin driven in one unit and carefully fitted to insure maximum capacity. Can be easily removed from exterior of engine as a unit.
- 15 OIL SCREEN**—On discharge side of pressure pump affording protection from dirt and insuring proper oil flow at low oil temperatures.
- 16 REJET VALVE**—Simple in design. Accessible for cleaning and impossible to improperly adjust.
- 17 VALVE TRIND**—Obtained by Vernier adjustment and maintained by positive ball drive.
- 18 CRANK CASE SCREEN**—Located in oil sump prevents possible damage to scavenger pumps.
- 19 MASTER ROD BEARING**—Full force lubricated through hollow crankshaft and assisted by centrifugal force, which force also carries to distant bearing surfaces in special aluminum tray insuring clean oil at all times to the bearing.
- 20 SNIFFLE RING**—Full force feed lubricated from master rod bearing.
- 21 CRANK SHAFT**—Generous cross section stress with bearings close to crank cheeks reducing stresses to a minimum and eliminating fatigue.

WARNER "Scarab" ENGINES

Pretty?

Listen . . .

. . . nothing prettier ever flew!

LEARN how to drive with a truck? How about a car? What YOU want is today's smartest radiator—full of pep and power and fight and go! Something that pumps when you touch the accelerator—something dashing and spirited—alive.

WHEN you climb into a Great Lakes Trainer for your first trip aloft, you know you're in an airplane! Give 'er the guns, ror away to a soaring take-off! Touch the joystick for a bank—there's almost human coordination between rudder and ailerons. Throttle 'er down for a slow, smooth, three-point landing. Boy!—that's life for you!

Learn your flying while they teach you in a Great Lakes Trainer and you'll never have to apologize for your school or your ship. Even if you start in something else, you owe it to yourself to complete your course in a Great Lakes ship. The Trainer is just about the neatest trick you ever cocked an eye over. Graceful. Fast. Rugged. And good looking as the girl in that blue roadster yesterday. Motor! An American Cirrus that roars an indication of its mighty power every time you open the throttle. Safe!—well, it's engineered to the strictest specifications—built by men who see fliers and know flying.

As a matter of fact, if you really want to learn about the air and the thrill of flying, the Great Lakes Trainer will teach you. Write for our new illustrated book, "Learning to Fly." It's free!

Very Truly Yours,
Detroit, Michigan.

Attention: Aviation Editor

Gentlemen:

The exceptional quality of the finish on the Great Lakes built The Great Trainer, general as a ship in this price group, is a subject of interest amongst everyone, in practically all sections here in the use of Berryloid throughout.

To say that although no one severely discriminated your product as the extent because of what we have of the experience of other manufacturers, it was subjected to competitive tests along with other finishes before acceptance, and proof of its superior quality on every count.

Another very noticeable product, General, is being used to protect the interior surfaces of the various submersible steel sailing ships. Come the passage of the Trainer, to find that you are to be congratulated upon this product as well.

Thanking you for your cooperation in the past and with best wishes for continued success, we are

Respectfully yours,

LOS ANGELES TO OAKLAND — GAS \$4.14

Engineers and Master Gullman have built standard into the EMSCO CIRUS — tomorrow's Cirrus motor has demonstrated its dependability. Now John Gullman, Master T. A. T. just brought an indisputable evidence of the economy of this remarkable combination of plane and motor.

Under normal weather conditions and with little or no wind, Gullman flew the body open and making nonstop from Downey to Oakland in three hours and 45 minutes. The airline distance is 350 miles and it took 18 gallons of gasoline to make the plane in its capacity of 30 gallons. That is 4.8 gallons per hour or 19.4 miles per gallon. Figure it up for yourself with aviation gasoline retailing at 22 cents per gallon.

The price of the EMSCO CIRUS is no more than that of the four motor cars and its ability to furnish economical transportation over great distances, direct compact use. Responsible dealers will be interested in the EMSCO sales plan. Details will be forwarded on request.

Why YOU should

CURTISS "TANAGER"

Winner of \$100,000 Guggenheim International Safety Competition

*First Successful Heavier-than-Air Cross Country Flight
by WRIGHT BI-PLANE 1909*

enter AVIATION

the Curtiss-Wright Way

Curtiss-Wright developments and achievements are today bringing the air mastery of the world to America.

This leadership was most clearly demonstrated when the Curtiss "Tanager" won the \$100,000 Guggenheim award as the world's safest plane. This brilliant victory in international competition not only proves the ability and soundness of Curtiss-Wright engineering, but also inaugurates a new era of safety in the air. "A plane that the lay pilot could fly with satisfaction, security, efficiency and safety," was the official summary of "Tanager's" ability.

THE development of the "Tanager" is only one of the many outstanding achievements by Curtiss-Wright in the past few months. Considered the first over the South Pole in a plane with Curtiss-Wright motors, Duke Jackson and Forest O'Brien established the world's new distance record of 31,700 miles in a "Baker" powered with the famous Challenger motor—both Curtiss-Wright products.

The "Hydrex" ship established the record as the fastest commercial ship ever built, winning the Cleveland-to-Boston a huge field of entries. It was produced by The Aircraft Division of Curtiss-Wright Group.

Curtiss-Wright engineers produced the "Biplane," the world's most famous test wing ship.

The airplane "Caudron" is a world-famous lightweight transport plane, carries passengers over the I.A.T. and other airlines.

MOHAWK adopts HEYWOOD STARTER as standard equipment

Mohawk—the well known light, low winged monoplane has adopted the well known Heywood Starter as standard equipment on all ships.

The selection of Heywood by Mohawk is in line with this company's rigid policy of choosing only the most dependable and equipment on the market.

The Heywood Injection Starter has gained its splendid reputation because it starts instantly under all conditions—in light or weight—has few moving parts and is as simple in operation as its design.

There should be a Heywood on your ship. Send for complete details.

SKY SPECIALTIES CORPORATION
2641 Hart Avenue Detroit, Michigan

START-ER by HEYWOOD

KEYSTONE-LOENING AMPHIBIAN "AIR YACHT"

Making three trips a day each way between Detroit and Cleveland, the Keystone-Loening Air Yachts of the Thompson Aeronautical Corporation flew 97,191 miles in seven months of last year—equivalent to four times around the equator.

With the waterfront bases of T. A. C. but 1.6 minutes from the business centers of both cities, passengers leave and are in the heart of the other... 100 miles distant... in a scant hour and a quarter. Small wonder that T. A. C. carried a full complement of passengers on a high percentage of the 972 trips made during 1934.

In the November issue of Aeronautics, Mr. Richard (Tex) Marshall, V.-P. and General Manager of T. A. C., said, "We decided to use Keystone-Loening Amphibians because we had faith in their sturdiness, their all-around

FOUR TIMES AROUND THE WORLD

ability as flying machines and because of their excellent records made in all

kinds of service." This choice was amply justified by the results T. A. C. obtained from these machines in actual service.

Keystone-Loening Amphibians are making profits possible for leading air-transport lines such as Pan-American Airways, Western Air Express, Curtiss-Wright Flying Service, American Air Express and many others. Full particulars showing the distinct advantages of the Air Yacht over other types of equipment gladly furnished on request.

OXWELD
WELDING & CUTTING APPARATUS

MORE welds were made with Oxweld No. 1 High Test Welding Rod during 1929 than during the preceding four years combined. This phenomenal rise indicates its general recognition and acceptance by Engineering and Industry.

The reasons—
It has proved uniformly dependable.
It is made to rigid manufacturing specifications.

Each lot is checked by actual welding tests.

It assures approximately 90 per cent. greater tensile strength than mild steel rod.

If you are not already using this rod it will pay you to try it

PROFITABLE LINKS in Air Transportation

THERE is one sure way to gain better than usual profits from air transportation. The sure business is a basis of safety, speed and comfort at low operating cost—with TRAVEL AIR Six-Place Cabin Monoplanes!

Throughout America there is a need for tributary air lines, to fill in the gaps between off-main-line cities and important airports on cross-country routes. Passengers will patronize a feeder line that takes them direct to a connecting airport without the delay of transfer from train or motor bus, and long-distance travelers like to continue their journey by air from distant points to destination. Such air travel truly saves time.

*In Travel Air at the
Curtis-Wright Exhibit
at the International
Aircraft Exposition,
St. Louis
Airway 226 is 226!*

Passenger confidence is won and held by TRAVEL AIR. In luxurious interior provides comfort and relaxation—riding pleasure that makes business and brings repeat business.

From the operator's angle, TRAVEL AIR Six-Place Cabin Monoplane is an ideal ship. It is economical—versatile—ideal.

line passenger and express service, in charter for business or pleasure trips, or as a reliable means of transportation for emergency when speed is especially important.

On every good point you can think of—handsome appearance— inherent safety—easy handling—all-weather efficiency—speed that assures low passenger-mile cost—TRAVEL AIR has demonstrated its superiority.

Write straight to headquarters for full information on TRAVEL AIR new planes for transport service and detailed statements of costs in actual operation. Address Dept. T-9.

A PLANE FOR EVERY PURPOSE

TRAVEL AIR

When eyes turn to the sky, minds turn to Continental, for it is here that the finest developments in aircraft engines are being created—in the vast plants and laboratories that have served so many users of gasoline power for 29 years.

"Approved Type Certificate No. 36, U. S. Department of Commerce"
CONTINENTAL AIRCRAFT ENGINE CO.
 General Office and Factory, Detroit, Michigan

Continental Engines

Drawing upon the facilities and experience of the greatest engine builder in the world, Continental is uniquely enabled to counsel with the trade in the design and production of engines to fit individual requirements.

EDO THANKS THE AIRCRAFT MANUFACTURERS

WITHOUT the helpful cooperation of the foremost aircraft manufacturers, EDO could hardly have won its justly deserved position as the world's leading maker of civil aircraft floats. It is working hand-in-hand with the nation's greatest aeronautical engineering staffs that has enabled EDO designers and craftsmen to produce float installations that are scientifically correct in design and performance.

To these aircraft manufacturers EDO is grateful, and pledges itself to continue to produce floats as efficient, as durable and as trouble-free—just as perfect as modern aeronautical science can make them.

EDO floats are now available in 11 standardized models suitable for land planes up to 8000 lbs. gross load, in accordance with U. S. Department of Commerce regulations. Already more than 40 distinct types of land planes have been EDO-equipped—with complete float installations interchangeable with the wheel landing gear. All of the planes shown on this page have been granted licenses as EDO-equipped seaplanes.

EDO invites the cooperation of other aircraft manufacturers—and extends to them the facilities and benefits of years of experience devoted solely to the design and manufacture of floats and their attaching gear. EDO is prepared to develop and furnish complete float installations for any land plane and ensures these manufacturers and their distributors unbiased protection and cooperation in developing a seaplane market for their machines.

The tested EDO Sales Man has proved a wonderful profit-builder—and enables manufacturers and dealers to cash in on the tremendous and ever-growing demand for convertibles—land or sea—planes. For particulars about EDO floats, and details of the EDO Sales Man, address EDO Aircraft Corp., 600 Second Street, College Point, L. I.

EDO
 THE FLOAT MAKERS

With infinite Care and Skill <<<

GOOD airplane steel cannot be supplied from stock. Rather, they must be specially developed, and manufactured with infinite care and skill, in accordance with the exact nature of the task involved. Throughout the special department which Bethlehem devotes to the manufacture of "Airplane Quality" Steels and Forgings this principle is held as fundamental. It is a governing factor in Bethlehem's success in meeting the requirements of the aeronautical industry.

Bethlehem's experience in developing and manufacturing steel and forgings for builders of aircraft engines dates from the beginning of the aeronautical industry. Many of the greatest flights in the history of aviation were made by planes with Bethlehem "Airplane Quality" Steels and Forgings in vital parts of their engines.

To the aircraft engine builder, Bethlehem offers steel of proved reliability—plus the services of an organization that is fully equipped and eager to cooperate with him, and in position to draw on a vast reservoir of experience in the development and manufacture of "Airplane Quality" Steels and Forgings.

With the aim of developing all-weather and better steel to meet the demands made of aviation and other industries, continuous research and experimental work is carried on in Bethlehem laboratories.

>> Make it a point to see the Bethlehem Exhibit at the International Aircraft Exposition, St. Louis, February 15-23, booths 61 and 62.

BETHLEHEM

"AIRPLANE QUALITY" STEELS and FORGINGS

Only two

out of 1730 prospects were "too busy" to see this flying representative!

A new product to sell... the largest and most up-to-date hotel in New York City. Hundreds of prospects to be seen... located in 60 cities in every part of the country. Only one man available... and a 19200 mile trip to be made in 10 days!

Obviously older transportation methods—the railroad or automobile—were far too slow. There was only one way to cover the ground, and that was to leave it. A Curtiss Robin was chosen. The trip was made—through rain and sun, storm and cold—without a hitch.

This was a carefully planned sales campaign. Letters were written to leading bankers, department stores, hotel operators and hotel managers—1730 in all. They were old when Mr. H. H. Brown, Assistant Manager of the New Yorker Hotel, would be in their city. Only two of the 1730 prospects were "too busy" to see the man who had such an important message that he flew it all the way from New York to deliver it. Even if these personal calls

had not been made, the "flying" trip would have paid for itself three times over in publicity value alone!

An unusual case? Not at all. Large enterprises now regard the airplane as essential business equipment—as the fastest they know of a man in two places at the same time. And every day more and more sales managers are turning to the Curtiss Robin for those important "flying" trips that must be made.

With more than 40 strategically-

located airports of the Curtiss-Wright Flying Service, and distributors practically everywhere, the reliable service that keeps planes in perfect condition—by Curtiss-trained mechanics—is never more than an hour or two away.

There's a definite need for a Curtiss Robin in every line of business—ways in which it might be used to increase sales and profits. For particulars as to how a Robin might best serve you, address Dept. B-77.

CONFIDENCE

BUILT ON

Constructive principles

You can do business with confidence when you buy of the General Electric Supply Corporation.

Our prices are definitely established.

Our merchandise is of sound design, material and construction.

Our salesmen are helpful counselors.

The product and service that we offer make buying a profitable action on your part.

The reputation of General Electric products becomes daily more and more visible. A billion advertisements feature them each year

—to serve better the choicest needs of America

—the public accepts them ever more readily—a majority of the American people already own and use equipment bearing the familiar G-E monogram.

The General Electric Supply Corporation supports the General Electric policy of constructive development for the industry and for the public it serves. With any one of our 81 Houses, you can do business with confidence. If you have an electrical need—write!

Join us in the General Electric Hour, broadcast every Saturday night at 9 p.m. Eastern Standard Time over a nation-wide N. B. C. network.

D. H. GYPSY Moth

Instruction's Greatest Ally—Ambition's Kindest Friend

TRIM of line, sturdy of construction, powered by the reliable Wright Gypsy engine, tested and found true in more than 10,000,000 miles of flying under every condition and circumstance, Moth planes are built for quick, safe, thorough training service.

Among the outstanding features of the Moth are: aero-dynamic stability so complete that the ship precisely follows itself—extreme immunity to stalls through Handley-Page slotted wings and D. H. differential stream—generous control surfaces, beam-land to give instant, easy and smooth response to the pilot's touch—steel-tube fuselage and wide, split-oleo undercarriage to withstand the severe shocks of inexperienced handling—structural factors of safety for above stress of the most extreme aerobatic flying—telephone system to permit normal voice in conversation or instruction. The Moth possesses many other extraordinary refinements that have received the approval of famous engineers and pilots.

See D. H. Gypsy Moth in the Center, Wright Air Museum International, at Dayton, Ohio, January 1939.

In a business and when economy is counted on profit, the Moth affords remarkably low cost of operation. The gasoline consumption approximates 18-20 miles to the gallon—about equal to that of the average automobile; all consumption correspondingly small. Rugged structural strength of plane and efficient simplicity of engine brings a welcome freedom from constant repairs and replacements.

These are facts. There are others that will interest you as greatly. Write today for Gypsy Moth records of endorsement, achievement of performance, figures of actual operating cost. Address Dept. 1673.

When You're Flying
for Pleasure—

Sit Side-by-Side in an Inland Sport!

COMPARING pioneer automobiles with today's cars, an outstanding difference is the degree of comfort afforded driver and passenger. Similarly, the Inland Sport brings greater comfort and pleasure to flying. The semi-reclining seating arrangement in a roomy cockpit makes the Inland Sport "tomorrow's plane today."

Pilot and passenger can talk face-to-face in arbitrary tones, even while flying at high speed. They can discuss their maps, consult one another about landmarks, point out the "inlets" on maps, converse as they would in a motor car. Sport flying thus becomes as pleasant, as charming and as relaxing as motoring in a sleek sport sedan—plus all the thrills of the air!

The Inland Sport is built for air-minded sportsmen... for you who desire flying who still harbor for the feel of a stick... for you by whom pilots in harness... and for schools. This high-wing, two-seater ship is the ideal training plane because of its side-by-side seating arrangement.

Sturdily built, the Inland Sport has the strength and ruggedness to withstand hard usage. It is economical in use... economical to operate. Powered with a LeRhond 60 or Warner Scarab engine, this small, low-price sport plane has few equals in refinement of design, beauty of line and color, performance and reliability.

ACCLAIMED!

The Greatest
Aerial
Life Saving
Devices
In the World

From all over the country flyers have written us saying they believe the Floyd Smith Safety Chute and Seat the greatest and most practical Aerial Life Saving devices in the world today. Not just another chute, but an entirely new departure in parachute construction, eliminating all "ifs" and "perhaps" and developed by the Daddy of Parachutes from years of experience, to meet modern flying conditions.

THE MANUALLY OPERATED PACK

Smaller, lighter, more compact—no flaps—no elastic bands—no fruit can poles—no tied parts exposed—making it get out of order, is it completely fool-proof. A single cable (ladder) gives a triple position opening action direct from the slip . . . a pull and out shoots the pack cover acting as pilot and instantly the main chute blossoms; not a chance of blooming under any circumstances.

THE SAFETY SEAT

This is the first practical life saving device for transport and cabin planes. A comfortable upholstered seat in appearance, in a moment it can be turned into a positive life saving device whereby twenty passengers can be dropped through the bottom of the transport in no more than a few seconds to earth, without a passenger moving from his or her seat.

SPEED - SAFETY - COMFORT - ECONOMY

The Buell line of Alcedos is created on the soundest business fundamentals of flying. Absolute safety is paramount; comfort and economy in both purchase price and operating cost are emphasized to the greatest extent consistent with safety; speed is a variable factor depending upon the choice of engine. Here is the ideal choice for "this business up above."

LEFT—The Buell Standard Alcedo is an eight-place dual, control plane, priced at \$12,500 with the Ford engine and \$17,500 with the Curtiss or Cyclone.

Buell Alcedos are writing many chapters in the history of the sky. Their most recent and most outstanding achievement was completed on August 23, 1928, when the Sun God (Buell Standard Alcedo No. GA-6-42) finished the first round trip, non-stop, refueling stop, from coast to coast—Spokane to New York and back again more than seven thousand two hundred miles under every conceivable weather condition.

LEFT—The Buell Standard Alcedo is a six-place, dual, control plane, priced at \$11,500 with the J-3 or right-hand engine.

Such remarkable records of endurance, speed, safety and economy as have been achieved by Buell Alcedos must surely be considered in determining your choice of a plane.

LEFT—The Buell Super Alcedo is a three-place, dual-control plane, priced at \$12,800 with the J-3 or right-hand engine and \$14,200 with the J-3.

Landing
on a New
Tarmac
Runway
Surface

2 Hours and 40 Minutes AFTER IT WAS FINISHED

Tarmac's function is to keep airports in operation as continuously as possible . . . to make them provide service and produce revenue, in spite of weather, climate and conditions of the ground.

True to that mission, Tarmac does not interfere with the operation of the airport even during the construction of the runways.

The illustration shows a section of runway surface at Bettis Field (Curtiss-Wright) near Pittsburgh, with a plane landing almost immediately after the workmen had finished the job.

Tarmac airport surfaces make landings safer and take-offs quicker. They eliminate dust in dry weather and mud in wet weather.

Tarmac is used for runways and taxi strips, landing strips, hangar aprons and for roadways leading up to airports.

Write for information on how to build Tarmac airport surfaces at low cost.

Illustration of a Tarmac surface, showing its porous, skidproof, non-dustive surface.

MAKES GOOD AIRPORT PAVING

FOKKER FACTS—I

THE NEW F-32 SLEEPS 16 PASSENGERS

THE FOKKER F-32 is the largest plane built in America. Its wing spread is 90 feet. It carries 30 passengers by day, and sixteen by night. Powered by four Pratt & Whitney 575 h.p. Hornet engines, its high speed is 140 m. p. h. and its cruising speed 120 m. p. h.

This giant Fokker airplane was evolved by the manufacturer who has built more planes than any other man or organization on earth, the manufacturer whose planes have made twice as many world-famous flights as any other make of plane, and whose planes have flown over 15,000,000 miles in America.

transport lines, establishing a record for dependability that has never been approached.

This plane was designed and built with the same surety and skill that pilots and transport executives have come to expect in every one of the ten models now produced by the affiliation of Fokker and General Motors Corporation.

Because of the useful carrying capacity—low operating cost, economical maintenance and low initial investment,

Fokker planes are today making it possible for air transport companies to compete with rail transportation at a profit.

For the use of business executives, for pleasure, and for emergency use, Fokker has made an important addition to a splendidly varied and well-balanced type of plane. Its planes, flying from, anywhere. Reports for information or demonstration are desired and will be promptly returned. Fokker Aircraft Corporation, General Motors Building, New York.

SAFE HARNESS

SUPPORTS YOU IN COMFORT—

THIS harness of an Irvin Air Chute is specially adjusted to fit the largest or smallest person, and is made of a specially woven linen webbing of 3000 pounds tensile strength. It is reinforced on all metal parts. These metal parts consist of the snaps and adapter buckles used in securing the harness and adjusting it for use. They are chrome-plated steel with a tensile strength well over 5000 pounds, and are either galvanized or cadmium plated.

Careful attention to details creates a strength that follows through to every part of an Irvin Air Chute.

Irvin Air Chutes are available in all sections of the country. Among the important distributors are Curtiss-Wright Flying Services, Colonial Flying Services, Air Associates, Inc., Nicholas-Brenley Engineering Company, Cleveland Institute of Aeronautics, Cleveland, Ohio; Pittsburgh Aircraft Agency

Corporation, Pittsburgh, Pa.; Leakington Philadelphia Flying Service, Philadelphia; Pico Motor Equipment Company, Wichita, Kans.; Walter M. Murphy Co., Los Angeles, Calif.; Aero Corporation of California, Los Angeles, Calif.; Southern Equipment Co., San Antonio, Texas; C. V. Stark Corporation, New York, N. Y.; and Mid-West Aviation Corp., Omaha, Neb.

Dealer who are interested should communicate directly with this company. If there are no dealers near you, write to us and we will arrange the most convenient way to supply your needs.

Like a University Degree

A DIPLOMA from the Airplane and Engine Mechanics School of Parks Air College brings you immediate returns. It is proof positive of your ability. For the aeronautical industry knows by getting experts that Parks-trained mechanics are experts—thoroughly competent to handle any job in the factory or on the flying line. The Parks course for mechanics is unequalled anywhere in the world, just as Parks flying courses are without a peer. Every subject is taught systematically—thoroughly—casualty-free. Every operation, from the fabrication of metal fittings to the building of wings and fuselages and the assembly of new airplanes, is performed under the supervision of instructors who are only a great institution like Parks can afford—and with the first and most elaborate auxiliary design and layout.

Every Parks course, too, is under the close personal supervision of Oliver L. Parks, whose fame as an experienced leader in the field of aviation instruction is international. That is another reason why Parks training means fast training—why a diploma from Parks gives

the same definite proof to its holder as a university degree. In its efficiency, too, Parks Air College offers its graduates more opportunity for employment than any other training school in America. As a division of the Detroit Aircraft Corporation it is a member of an organization that includes five of the finest aircraft factories in America. They are needed—and will continue to be required—by Parks mechanical. Another assurance of the future of the Parks-trained man!

You, too, can be a Parks graduate. You, too, can know the success that comes with the finest training in the world. The coupon on this page will bring to you the fullest information about Parks and its courses.

Get it in the mail **RIGHT NOW**—and we shall send you "The Man Who Tames the Plane", a vivid, interesting picture of the mechanic's highly profitable place in aviation. Don't forget the coupon is your ticket to a new viewpoint on aviation—to an hour of absorbing reading—to success in the new, most fascinating and best paying of the world's great industries.

Parks Air College was one of the first to be licensed by the U. S. Department of Commerce as a fully accredited transport school.

BUSINESS MEN ARE CHOOSING

STEARMANS

★ Watch Fenestra and the other
Stearman owners during 1930

UNDOUBTEDLY an tribute to Stearman—

the fact that aggressive business men, such as Mr. A. W. Sawdon of Fenestra (The Detroit Steel Products Co.), chose a Stearman for his 1930 business task. For business, the Stearman is well suited. All pilots say so, too—short landings, quick take-offs—climbs nicely with a heavy load. Just a matter of a few hours—for a trip from Dallas out to the oil wells—from the factory (Detroit) to a hot prospect in Des Moines—from Mexico City to Laredo—from New York across the Sound to New Haven—Stearman is the choice. Business Speedster or Junior Speedrail series is adaptable to sport or commercial flight. Wire or write us at the factory—see us in Section F, Building B at the International Aircraft Exposition, St. Louis, February 15 to 23, where our attractive sales franchise for 1930 will be explained. STEARMAN AIRCRAFT CO., WICHITA, KANSAS, Division of United Aircraft and Transport Company.

An ancient process, proper forging is still the accepted way to put maximum strength and endurance into parts of decision.

Brood Technical Knowledge . . . Mastery of Design . . .

THE CHAMPION MACHINE & FORGING COMPANY
6155 East 14th Street
CLEVELAND, O.

CHAMPION DROP-FORGINGS

It takes off in 50 YARDS

... but that's only one reason pilots in 16 countries call it the world's SAFEST light plane

FIGURES show that rate of crashes accounts for 12% of all airplane accidents in this country

That's why Avian engineers gave the Avian perfect take-off performance

The designers cut its weight to only 875 pounds—including the 55 h.p., Curtiss air-cooled engine that holds more records than any other light plane motor in the sky lines.

The Avian's cushiony, split-side undercarriage absorbs bumps running over the bumps of ground. Its Handley-Page wing also permits the pilot to pull as close up sharply without danger of crashing from a roll.

Just sit a hip in an Avian. Turn to the runway—it handles like an automobile. Then give it the gun. What power! What position of control! You're ready to move up before you can say "Jack Robinson!"

Throughout the flight, the Avian insures supreme safety. Its structure is 4 times stronger enough for actual flight—a structure that enables it to start with the ease of a parasol plane. Yet the Avian will not spin, for those automatic spin machines that ship with little loss of altitude and speed.

For landing, the Avian requires only a small clearing. It sets down gently on 3 points at the amazingly low speed of 15 m.p.h.

Here its downright safe performance that no other light plane can equal. And economy that can't be beaten—the Avian makes every gallon of gas give 20 miles of travel. You can now buy an Avian for about \$1750.00 down and balance in monthly payments. Write today for full information on the plane that's built for quiet, safety and economy.

To Dealers and Distributors

When you fly or sell the Whittelsey Avian you have something to sell about. No other light plane has such a record of performance... as the airplane. Dealers and distributors are still being appointed. Write for our sales plan, and for full data and specifications of the plane itself. The Whittelsey Manufacturing Company, 231 Howard Avenue, Bridgman, Mich.

Show Time Again

THE AERONAUTICAL WORLD is converging, as these lines appear, upon the St. Louis Arena. For the first time since last April we are coming together for an indoor show with no flying competitions attached. The period of ten months that has intervened has, we believe, been more fruitful with consequences for the airplane industry, and has given us a better idea of its real ultimate status, than any other like interval since the War, not excepting the historic days of the Lindbergh flight.

We are in the last stage of the transition of aviation from a "passé" into a genuine industry.

The builders of aircraft and their parts and accessories, and those who are interested in their operation, are coming to the Show as a spirit of determination to know the whole truth about themselves and their business, whether it be pleasant or otherwise. That fact is the most encouraging sign upon the horizon. Never before has there been greater sincerity of purpose. Never has there been a clearer realization that the interests of the whole industry is one and together. We shall be very much surprised if the meetings of the Aeronautical Chamber of Commerce, and especially its discussions with the personnel of the Aeronautics Branch of the Department of Commerce, are not better attended and productive of freer discussion than ever in the past.

We have learned a great lesson about selling in the last year, but there is much yet to learn. The purpose of an aviation show is not to harvest a crop but to plant a seed. The advantages of selling a few individual airplanes by dint of seeking diligent whoopees in company with the prospective purchasers are negligible compared with the benefits that can be derived from showing the aviation industry in a favorable light to a large group of intelligent visitors and from starting

dealers off on the right foot for the selling season. The dealer in airplanes ought to come to a national show with the object of presenting a collection of useful ideas. Both the airplane and the automobile industries and others as well, have unfortunately been capably furnished in the past with dealers who saw in a show primarily an opportunity for getting behind on their sleep and accumulating a series of headaches.

There is always a tendency to judge the interest of an exhibition by the number of spectators that come to see the display. We are in a position to realize that there will be no dearth of novelties at St. Louis, but that is no measure of the importance of the affair. The Show would still deserve attention if the interest development for the year had been purely evolutionary and of the slightest character, or if all of the new models that are to be on display had been announced weeks ago. It is, in fact, the little things that make the show most important. Revolutionary modifications can be seen quite as well from drawings and photographs and written descriptions as by examination of the structure "in the flesh." To appreciate the changing art of design in aircraft design, however, one must have the products of the whole industry conveniently available for direct comparison.

The Show is serious business and every possible benefit should be drawn from it as well, but it is imperative not to feel a little holiday spirit as one starts for so pleasant a gathering of all the aeronautical talents. As we push our machines and leave a hurried instruction for handling mail in our sleeves, our minds (if we are vulnerable enough to permit) turn back a quarter of a century. Our steps unconsciously grow a little jaunty, and we swing away towards the airport or station to the lulling refrain of "I'll meet you in St. Louis, Louis meet you at the fair."

A FORECAST OF THE *St. Louis Show*

Plans of the Exhibitors in

Brief, List of Exhibitors and Program of Events

By

LESLIE E. NEVILLE
Technical Editor of AVIATION

Flight photo of the Kiowa powered biplane shown at the New Standard Aircraft Show.

WHAT IS EXPECTED to be the most extensive exposition of American aircraft products ever held will be officially opened this evening (February 15) at the New Arena in St. Louis. Two hundred exhibits comprising nearly 100 airplanes and a large number of engines and accessories constitute the 1935 International Aircraft Exposition sponsored by the Aeronautical Chamber of Commerce of America.

As the task of writing the program calls for a mass flight of 40 airplanes to fly over St. Louis, taking off at noon and, in order that demonstrators may be made and planes may land adjacent to the arena, runway on a flying field at Forest Park are being got into shape. A colorful retrospective depicting the history of transportation in which more than 200 pictures will participate as to be held each night during the show period from February 15 to 23.

One of the principal purposes of this exposition is to set on a permanent basis a national manufacturing program in the aeronautical industry. National conferences on aeronautical education under the auspices of the Aeronautical Chamber of Commerce in cooperation with the David Guggenheim Panel Committee of Elementary and Secondary Aeronautical Education will be held during three of the nine days' gathering. Numerous trade and engineering conferences will take place during the show.

Nearly a dozen new models of aircraft will be introduced at the show and, according to present indications, a larger proportion of airplanes with floats, ice planes, amphibians and gliders will be shown. It is

expected that greater refinements in airplane interiors, more outboard engines and parts, and more structural exhibits will be staged. A brief review of the plans for the various exhibits is presented below.

Airplanes

Among the airplanes to be exhibited for the first time at the American C-2 is a single and monoplaned of unique design intended for the flying student who wishes to acquire sufficient time to obtain a transport license. Its power plant is a two-cylinder opposed engine rated 30 hp at 2,500 r.p.m.

This exhibit is sponsored by the Aeronautical Corporation of America. Although previously shown at various local exhibits the Savoie Marchetti S-35, three place amphibian biplane, is being shown for the first time at a class A exhibit. This airplane, which is powered by the Kiowa K-5 engine, is being purchased by the American Aeronautical Corporation which also has manufacturing rights in America for other Savoie Marchetti designs.

Five airplanes will be shown by the American Eagle Aircraft Corporation and the features of the exhibit will be the new four place American Eagle monoplane pro-

vided with the Wright J-6-5 or J-6-7 engine. This airplane was designed by Stanley Wallace, chief engineer for Wallace Aircraft Company, Inc., a division of American Eagle, and is of the folding wing type intended to store in a space 13 x 25 ft. Two forward and one rear door are provided for entrance to the cabin and a large portion of the center section is made transparent.

A rear view of the American Eagle.

Through the use of non-shatterable glass, a considerable amount of this material is used in the cabin structure to obtain desired visibility.

Two "Pacemaker" monoplanes are equipped with folding gear and the other with floats, will be displayed by the Bellanca Aeronautical Corporation. These 1935 models are powered with the Wright J-6-9 engine and are available not only in six place planes but also as combination four-passenger and freight carriers. This transformation is made possible through the elimination of the two central

passenger seats of the cabin and the substitution of a 34 cu ft. metal freight compartment and in this form the design is known as the Pacemaker Freighter. An interesting feature is that the weight empty of the craft is 2,200 lb. and the useful load 2,300 lb.

The J-6-9 powered Standard American manufactured by the Hald Aircraft Company, Marysville, Wash., will be shown by that company at the exposition and the record breaking plane of this type known as the "Spokane Stinger" is to be on the field for demonstration purposes.

Realizing the increasing popularity of gliding as a sport, the Cessna Aircraft Corporation is planning to exhibit a craft of this type in addition to its regular airplane models DC-3-B and DC-4-A. Another feature of this exhibit will be a section of the Fairchild Cessna wing.

Suspended from the ceiling of the arena by a steel cable will be a Challenger powered Command-Aire biplane with Edo floats. This plane will be demonstrated by a Cessna-Edwards spotlight. An unusually attractive black and white color scheme is planned for the suspended plane. On the floor of Building B will be another Command-Aire plane powered with the Lycoming engine and embodying other construction features that are new to Command-Aire designs. In this airplane the undercarriage has been changed and the tail group has been somewhat modified. A third Command-Aire plane powered with the Warner Scarb engine will be located either at the show or at the airport.

A very comprehensive and complete exhibit of aircraft has been announced by the Curtiss-Wright Corporation and will include more various airplanes ranging from the three place open highway type to the Cessna engine-passenger transport. Among the other planes in the exhibit will be the Curtiss Tanager, winner of the Guggenheim safe aircraft competition, the Travel Air

The J-6 powered portable 40' Command-Aire.

low wing monoplane which performed so creditably during the National Air Races at Cleveland, the Curtiss Robin, the Keystone Excursion Commander and the Keystone Petitioner. The most recent addition to the Curtiss line is the "Kingfisher," a two-seat cabin monoplane powered by two 16-7 engines and embodying several new features in aircraft construction. It is the possibility that the Carrier Pigeon II, an unusual span staggered biplane intended for mail carrying, will be shown. This craft is powered with a twelve cylinder General Continental engine and is characterized by a fuselage of the semi-monocoque type constructed in three sections built separately and bolted together.

The D-10 monoplane manufactured by the Detroit Aircraft Corporation is to be shown and is worthy of mention because of the unusual aerodynamic features of its wing. It will be remembered that the wing action of this plane is a Göttingen 387 at the left wing attached to the fuselage and tapers into a Clark Y at the outer section and a modification of the Clark Y section at the tip.

A HIGHLY IMPRESSIVE exhibit in long display by the Detroit Aircraft Corporation. One of the features of which will be the unveiling of the Ryan Four-seater on the opening night of the show. The Four-seater is the 1950 model of the Ryan division of the corporation and is a four place plane built along the general lines of the previous models, having an unusual interior arrangement. Back of the front seat is designed to fold down giving the rear berth, having a comfortable lounge, while the other seats are all adjustable to reclining positions. The wing of the Four-seater is made in two parts for greater ease in handling while a number of improvements have been made in the control system. It is powered with a Wright J-6-7 engine. The Ryan division exhibit inside the new Ryan Wing, a six place cabin monoplane.

Other features of the Detroit Aircraft exhibit will be the display of the Lockheed Sirius, low wing open nose plane and duplicate of the plane recently designed to Col. Lindbergh and the standard Lockheed Vega. The Curtiss division of the corporation will show the latest Challenger powered Eastern flying boat and two of the airplanes manufactured by the Pacific division also will be displayed. A training glider will be included and a new model of the proposed MC-25, a new metal clad disposable capable of carrying 100 tons also is to be on display.

FOLLOWING a long period of development the Douglas Skyhawk, most recent creation of Ivan H. Douglas, chief engineer of the Douglas Aircraft Corporation, is being introduced to the public at the St. Louis Show. The Skyhawk, which is powered with the Rover four cylinder inverted-in-line engine, is a highly staggered biplane with modern seating arrangement. Wings are fabric covered over wrapped aluminum alloy ribs and spars span and the fuselage is the conventional steel tube type with cockpit reinforced with circular rings of large diameter steel tubing for safety to personnel and to eliminate wave through the portion of the fuselage where normal bending cannot be placed.

THE EXHIBIT of Fairchild Airplane Manufacturing Corporation will be featured by the model 42 Cockade Four-seater, a high wing cabin monoplane powered with the Wright J-6-9 engine. This plane embodies the Fairchild folding wing and has interchangeable wheel or

rotation gear. In addition to this plane the Fairchild 71, KR-34 and KR-20 also will be shown.

The central model of Kinner powered Fleet airplane will be exhibited together with facilities gear for use in connection with this craft.

Models of the Standard Universal, Super Universal and F-10-A trainer. Fordair airplanes will be shown

The three-bladed propeller which is now being produced by the Ryan Manufacturing & Foundry Company.

with no radial changes from accepted practice in the exhibit of the Fairchild Aircraft Corporation, Division of General Motors Corporation.

Two autogiros, one powered with the Warner engine and the other with the J-6-3 Wright power plant, will be exhibited by the General Aircraft Corporation, the corporation of that company having made it impossible to purchase the model 109 biplane for display at the show.

THE Great Lakes Aircraft Corporation is departing from its practice of the past by exhibiting only one airplane instead of several. This craft, a Trainer model 25-1A, is to be displayed as a show plane and in addition to blue and gold finish and chrome plated trimmings will have a special instrument board built by Pioneer and designed so that all dials are placed in a manner that their pointers indicate toward the center of the board under normal conditions. The front cockpit of the plane will be covered over to form a baggage compartment.

Two aircraft, one an amphibian and the other a flying boat will be shown by Inland Aircraft, Inc. One of these, the N-3-C five place cabin amphibian has been in production for some time, while the other, the M-3, two place open flying boat, is a very recent development. The larger amphibian has an all metal structure with fabric covering and is powered by the Pratt-Wright Wasp engine. The smaller is powered with the Leffland 60 and is available with amphibian landing gear with the Leffland 50. Gyro, Cigar, Cigar and other organs of the same horsepower range. The hull has a wood structure and skid skis. The M-3 is an externally braced monoplane, while the N-3-C is a biplane. Wing ribs, tail ribs, and many other parts are interchangeable on both crafts. It is interesting to note that both planes are pushers.

Three airplanes, all two-place open cockpit biplanes and powered with the OX-5, Kinner or Warner engines will be exhibited by the Laroche Aircraft Company, Inc. These airplanes are all of conventional construction.

The new Mohawk Pats with a number of refinements over the previous model will be shown. Among the

improvements are dual instruments in front and rear cockpits, individual doors for passengers and pilot, and large inspection windows under the wings and fuselage.

A new addition of two-place cabin monoplane will be exhibited by the Moss Aircraft Corporation. This plane, which is to be the outstanding model of the Moss Aircraft line for 1958, is powered with the Lambert R-266 engine, successor to the Lambert Vult M-5 engine.

THE new Standard Aircraft Corporation will display the model D-25 at the show and the model D-39-A Trainer will be either at the show or at the airport. These airplanes are noteworthy because of the somewhat unusual use of open section fuselage in the fuselage. The Trainer is the latest model to be brought out by this corporation and several have been ordered by the Navy.

The Bunting NB-3 low wing monoplane, manufactured by the Nicholas-Bentley Airplane Company, will be shown. Three of these completed airplanes as well as a number of structural parts will be included in the exhibit. The new PA-7 Mustang, a refinement of the Pacer PA-6 plane, will be shown by Pacer Aircraft, Inc. Improvements include rounded wing tips, special retractable landing lights, a new method of towing the engine and a new arrangement of instruments. Announcement has been made by the Spartan Aircraft Company of its plan to exhibit the new Spartan D-3-25 biplane powered with the J-6-7 Wright engine. This is the second Wright powered Spartan airplane.

Three Curtiss powered by the Kinner engine will be exhibited by the St. Louis Aircraft Corp. The Curtiss is a two-place externally braced cabin monoplane of conventional construction.

Two new Seawind models will make their debut at the exposition and will be shown together with other exhibits of the United Aircraft & Transport Corporation. The Seawind Sponder follows closely the familiar C-3-B and is characterized by improved streamlining and additional instrument equipment. The most recent model of the company is the Seawind Junior. It will be available with either the Pratt & Whitney Wasp Senior, Wasp Junior or Wright J-6-9. A number of other improvements are included.

Six models constituting the 1950 line of the Stinson Aircraft Corporation will be displayed by this company. All of these are closed monoplanes. The group is to include three models of the Stinson Detourer Junior, one powered with a J10 by Lycoming engine and the others with the J-6-7 and J-6-9 Wright engines. Two models of the Stinson Detourer Senior will be shown, one powered with the J-6-9 engine and the other with the Pratt & Whitney Wasp Senior. A feature of the exhibit is to be a tri-engine plane recently developed by the company. In connection with the Stinson Junior it is interesting to note that Aeromarine channel section struts are being used in the wing structure which is a departure from previous practice.

A THREE-ENGINE de luxe club plane will be shown by the Stout Metal Airplane Company, division of the Ford Motor Company, and will be fitted with complete night flying equipment, electric starter and electric fuel pump. The power plant is a three Pratt & Whitney Wasp engines. The exterior finish, called "Birds Eye," produces the effect commonly found on the inside of wagh cases. The interior may be fitted with six special reclining chairs, four of which are so grouped that a card table may be attached to their arms. A folding berth

is located in the high ceiling portion of the cabin and arranged so that it may be added up into the ceiling when not in use. Directly below the berth is a small lavatory. In the after portion of the cabin is a complete kitchenette equipped with bar glaze, thermos cups, kitchen sounds, sink and drainboard.

The latest model Air Coach will be exhibited by the Verville Aircraft Corporation. This plane is powered with a Wright J-6 engine and has several novel features.

The usual display of current models of the "222" Straight Wing and "225" Taper Wing biplanes are to be exhibited by the Waco Aircraft Company and a number of major improvements have been made in the current models with no radical changes, in accord with usual Waco policy. It is planned if possible to introduce the new Waco 110 which is the latest model and has been developed along the general lines of its predecessors.

The exhibit of the Whitney Manufacturing Company will constitute the new Whitney Avion which

Cooling design by the Wright Aircraft Corporation for the Gypsy engine.

differs from the British production model in that it is constructed with a welded steel tube fuselage and has certain other minor modifications in the structure. This plane will be featured with Handley Page monocoque skins having half bearing and torque tube control mechanism.

Engines

THE EXHIBIT of the Aviation Aircraft Engine Corporation will be similar to its display in past shows and it is planned to adhere to a three-color scheme of moderate application throughout. It is contemplated that the company is planning to exhibit more working parts than have been here before, while a group of extensive manufacturing photographs also will be displayed.

The Brownell Tiger C-600 which is now being produced by the Lytle Manufacturing and Foundry Company is to be included in the engine exhibit. The Brown-

back engine is a six cylinder staggered radial type developed by the French firm, Motre Laboratories.

While no new features are noticeable in the engine to be exhibited by the Cassat Engine Corporation, an original method of presentation has been developed by the company. This is known as the Cassat "orientation booth" and its main feature is that it is easily disassembled and erected and can be set up in a matter of minutes in either seated and shod spaces. This booth with appropriate trimmings and draperies will be used to display the Cassat engine at St. Louis. Following to some extent the practice commonly employed at automobile shows, the Continental Motors Corporation will display a roadway model showing the covering parts of the A-70 engine in sections. In addition there will be an assembled engine and an exhibit of the separate parts.

THE NEW six cylinder in-line inverted air-cooled 6-370 engine recently completed by the Fairchild Engine Corporation will be one of the features of the Fairchild exhibit. This engine recently completed a 90 hr. one-stop test run at 9,110 full load and at full throttle alternately and the company plans to produce it in the near future.

Spans 227-230 will be occupied by the Kinner Air plane and Motor Corporation and the exposition will be the occasion for the announcement of the new Kinner five cylinder radial engine model R-715 which is now being placed in production. Units, parts and assemblies of Kinner engines will be displayed along with several K-5 models and a special runway of the engine.

It is planned by the Lambert Aircraft Engine Corporation to display the new model R-260 five cylinder radial air-cooled type, the most recent creation of that company.

A number of changes resulting in increased horsepower output have been made in the Licensing Aero Engine and these will all be clearly shown at the exhibit in St. Louis.

An interesting point of display is planned by the Michigan Aero Engine Corporation for the Rover five cylinder in-line inverted power plant. The new Rover model R-267 is somewhat similar to its predecessor but is a

number of refinements and an appreciably higher rated output.

THE WARD JUMBO, together with the Senior model, will be shown in a position to indicate their comparison in the exhibit of the Pratt & Whitney Aircraft Company. This together with the Senior B1 Heron and other engines of the company's line will feature the exhibit. A special Pratt & Whitney designed manifold cooling will be shown for the first time. This cooling and collector combination consists of a new cooling with adjustable skaters, a collector ring on the rear of the engine and a turning which serves as a preheater combination on the rear of the engine. Suitable connections and controls are provided.

Two new L head radial engines, an improved development of previous models, are to be exhibited by the Society Aircraft and Engine Company. These engines are successors to the previous three and five cylinder engines manufactured by the company. The 1930 model of radial engine manufactured by the Warner Aircraft Corporation also will be shown.

THE Wright Aeronautical Corporation will feature its temper line of engines in Building A. It is planned to show a six-cylinder J-5-D engine together with the completed models and the feature of the exhibit will be an improved cooling for the Gypsy engine. This cooling, which is furnished as standard equipment with the engine, is designed for simplicity and accessibility as well as effective streamlining and cooling. Spool shaped programs are provided for mounting the engine and will be shown clearly in the exhibit.

Aircraft

THE Aero Supply Manufacturing Company, Inc., in conjunction with its subsidiaries, Standard Aircraft Products Company and National Steel Products Company, will exhibit an full line of aircraft hardware and detailed fixtures. More than three thousand items are included in this line. A feature of the exhibit will be the Berrow fuel pump which has been designed to supersede the J-2. The replacement of the Air Motor Corporation will be the installation of the air filter manufactured by that company on a number of planes at the show.

Recent developments in aircraft and weather instruments will be featured by the Consolidated Instrument Company of America, Inc. This exhibit will include special custom built instrument panels for a number of standard airplanes, as well as complete airport equipment for weather stations. Standard types of instruments will be shown in actual operation.

The new type S-13 4-rod timing gear type of starter manufactured by the Kinner K-3 engine is to feature the exhibit of Elysee Aviation Corporation, Division of Bendix Aviation Corporation. Other starters ranging from 84 lb. weight upward also will be shown. Aircraft radio developments including a double voltage, voltage regulated engine driven generator and a dynamotor will be included.

In addition to the large number of airplanes to be exhibited with standardized Edo floats, the company will maintain a separate exhibit showing the latest standardized models. The display will feature a model J-3300, one of the larger standardized lines and a conventional model 1325 that installation which will include two of the smaller standardized floats together with all the necessary struts and strapping fittings.

AVIATION February 21, 1939

AVIATION February 21, 1939

A display board showing drop forgings for roller bearings, axle, exhaust flanges, engine gears, manifold clamps, and a number of fuselage parts, will be shown by the Eastman Forge and Manufacturing Company, Inc. Although no plans have been made by the Peter Bearing Company exhibit, this firm will have their newly developed standardized ball bearing and several of the planes of the company, notably Blenheim and Stearman, and the fuselages and the pylons being exhibited by the Westinghouse Electric and Manufacturing Company along with its other products.

THE CENTRAL FEATURE of the exhibit of the Fairchild Aerial Camera Corporation, the new Fairchild F-4, an all purpose product intended for a wide variety of work in commercial aerial photography. In addition to this, the exhibit will include several military types of cameras, one of these the model 35-1 being fully automatic, operated with a wind driven camera. The model F-4 which takes one vertical exposure and three oblique photographs at the same time, also will be shown. This camera is also supplied with a revolving prism which changes the oblique to vertical.

A display board upon which will be mounted instrument panel equipment for engine instruments, indicator magnets compasses and other aircraft devices will be shown by the General Electric Company. Working exhibits of complete engine compasses, air immersion heaters and propane gauges will be shown as well as a wing leading light designed to be built into the leading edge of airplane wings. In the aircraft lighting field will be shown a glass disc heater, a rotating beacon, illumination and boundary lights, approach lights and type ALF airport floodlight; an electric code beacon, a crating light and immersion lights, supplemented by a type L-13 lamp. Roadlights which complete the display.

Various sizes of air struts for airplanes will be displayed by the Grass Air Spring Company. A motion picture showing the complete action of the Grass Air Strut on an airplane will be a feature of the exhibit.

Spans 97 and 98 have been reserved by the Hamilton Standard Propeller Corporation, a division of the United Aircraft and Transport Corporation. The display of this company includes propellers for the smallest and largest airplane engines now in general use. In the low horsepower range, the company will exhibit the new light weight models weighing from 25 to 35 lb. and for the large gas turbine engines of 300 to 600 hp., a sample made from a propeller 13 ft. in diameter will be shown. Samples of service equipment will be on display and a number of runway models will be included.

NACA cowling, wing tips, wheel fairings, propeller nuts and other special metal parts will contribute to the exhibit at the HMI Aircraft Structures Corporation, an outgrowth of the Hill Aero Body Company which made its debut into the aeronautical field just recently.

AERONAUTICAL innovation in the parachute field is the new Quick-Connector type which is to be introduced by the Irving Air Chute Company, Inc. This new development is intended primarily for dived airplanes and makes it unnecessary for the wearer to wear the parachute except when necessary. The harness is worn at all times by the passenger and the pack placed on a convenient hook on the arm rest. The harness is essentially the same as the standard type except that suspended from the shoulders of the wearer and in front to a line slightly above the waist, are two safety hooks

or snaps. These are two small metal bars on the top of the pack and they can be quickly attached to these safety snaps with two quick natural movements of the arms, it only being necessary to pull the pack back against the breast of the wearer so that the two small bars catch

Sketches of the new parachute designed by the Irving Air Chute Company.

into the snaps. In other respects the parachute is of the same type and quality as that made by the Irving Company.

The new Lancer No. 8 goggles designed in an attempt to overcome air leakage and too tight adjustment will be shown by E. B. Meyer, Inc. Other features of these goggles will be reduction in weight of frames which are of aluminum alloy, a new patented clutch type adjustable bridge, and an improved venting system. An especially designed set of goggles and an elaborate layout of parts and supplies for airplanes and engines will be shown by the Nicholas-Bellows Airplane Company, Inc. Instruments, lights, trim, propellers and engine parts representing a total of no less than thousands of articles are to be exhibited according to the company announcement.

SPECIAL new instruments will be shown by the Pioneer Instrument Company and will include electric tachometers, push indicators, an altimeter in which both pointer and dial can be made to rotate at the same time if necessary, and some of the most recently developed navigation equipment. The electric altimeter consists of two axons, a generator and an indicator, the former being driven by the engine and connected directly to the altimeter drive and connected by two electric conductors to the indicator on the measurement board. The push indicator consists essentially of a pendulum connected to a gyroscope which is kept in rapid rotation by an air jet.

An entirely new model of aircraft radio beacon receiver representing a distinct improvement over its predecessor will be introduced by the Radio Marine Corporation of America. This display will also include a communication receiver for use in aircraft together with two new models of aircraft transmitters, all of which are designed for both land and remote control and operation. From such a dynamo, engine driven or wind driven generator. Of interest to airport operations will be the signal weather receiver especially intended for reception of Department of Commerce voice broadcast of air, weather and landing field conditions. Transmitted equip-

Wasp engine recently developed by Pratt & Whitney.

the strengthening of the industry's financial foundation through further consolidation and the elimination of many ill-considered activities.

Consolidation, which is the great trend, shows as clearly as that the majority of present types of airplanes used on airlines are uneconomical from the standpoint of the air transport operator. There is still much to be done by the aircraft designer and manufacturer to provide an airplane which can be operated at a minimum of cost and I look forward to much improvement in this respect during the coming year. The aircraft has lately been scratched in the matter of aerodynamic efficiency and too much effort has been directed on the part of production in comparison with that directed toward refinement and improvement of design. New indications are that the engineering of the airplane is moving some of the much needed structure and that central improvement in efficiency may be looked for.

2. The first half of 1932 saw aircraft production activities expand beyond all reasonable bounds as a result of an exceptional enthusiasm leaving perhaps 2,500 unsold airplanes on the market.

This soaring inclination will bring about a more carefully planned and regulated production of aircraft, and a more thoroughly organized and better directed sales effort.

Sales of aircraft for replacement purposes, with especial reference to scheduled air transport operations, probably will not be great. Many of the airline operators have found themselves with surplus equipment on their hands, and equipment in use during the last year was not flown enough to make replacement necessary. Obsolescence rather than wear and tear probably will be responsible for most of the replacements of transport lines during 1933.

3. The problem of resistance of production and sales to prevent undue seasonal slumps is a matter which requires intense study. Even the automobile industry with its much longer experience has seasonal production slumps, in which factories all but close their doors. Certainly the aircraft industry has as even more serious seasonal problem to consider.

4. Probably the largest present field for the sale of aircraft is that of unestablished commercial operations. There, I believe, sales efforts can be directed most effectively for some time to come. In the coming years there are hundreds of business opportunities which could be attractive to distant venturing, but which executives are not yet sold on the idea of flying as a means of transport an airplane. This field it seems to me, has untold possibilities for development.

Development of the private owner field, I believe, depends largely upon the manufacturers themselves, and upon their success in bringing forth an airplane suitable for private flying—that is, an airplane comparatively easy on the hands of the owner, an airplane which the private pleasure-flyer owner can learn to fly without undertaking a long costly flying school course. I do not believe that the field of the private owner will expand very widely until such an airplane has been developed and well proved and maintenance costs can be materially reduced. Development and encouragement of flying, I believe, will do as much as any one thing in preparing

a fertile field for the presently owned pleasure airplane.

5. As in types of planes, there is no question but that the three-place open plane has a wider field of usefulness than the two-place ship. The two-place job has its field limited largely to flying recreation, while the three-place plane can be used both for instruction and solo-flying and is much more desirable as a pleasure plane. I believe that, as with the automobile, the closed cabin plane will find greater favor in the future than the open cockpit type. There are numerous reasons. The closed ship is decidedly more comfortable, thus a protection from the wind blows and protection from cold in chilly weather. The cabin is easier to get in and out of than the open plane. There is more room, and certainly a cabin can be kept much drier than an open cockpit—a selling point for most owners.

Military Aviation—Air Mail—A Needed Readjustment in Progress

By FREDERICK R. RENTSCHELER
President, United Aircraft & Transport Co.

NEW PROSPECTS have been reached in 1932 by all branches of the aeronautical industry. To a certain degree, this increase was due to healthy expansion, but in some extent came about as a result of a public income being expanded. Laterally speaking, those of us with longer experience in aviation, and whose confidence in its future almost overflows of at far years almost overnight become pessimistic by comparison with the uncommitted optimism and beliefs on the part of less experienced individuals. Money and facilities were freely made available for both the need and unusual equipment and transport projects.

As a result of the above, the readjustment period now occurring was only to be expected. Aviation is at a present art, with vectors only available to the well trained, experienced aviator, and with the program still upon planning and engineering ability.

The art is by no means standardized, but is moving perhaps more swiftly today, from a development point of view, than ever previously.

Military aviation is still the backbone of the equipment industry, and remains strongly in the air as a basis of reference to transportation. Commercial aviation has made wonderful progress, and there is less question than ever that it is rapidly developing into a great new industry.

During this period of readjustment intelligent and conservative management in aviation is at its best. It is to be expected that in this period ahead the need and unusual projects and organizations will be clearly indicated and the usual results will invariably follow.

It is believed that there is more reason at the present time for complete confidence in the aviation industry than at any time during the twenty years of its existence. Military and naval aviation have completely demonstrated their worth. Types of airplanes and of engines have been tremendously improved in every way, which makes the possibilities for purely commercial projects greater

than ever. With the readjustment period behind us, aviation within 1933 will continue to show remarkable progress and continue toward its goal.

• • •

Sounder Financing and Larger Net Profits

By E. K. EVANS
President, United Aircraft Corp.

THIS INDUSTRY as a whole has just completed a very successful year in its history of growth, but judged by the standard of net income—which determines the success or failure of any industry—aviation has not been as profitable as we who are in it would like to have it.

We need, nevertheless, to have a more penetrating through in terms of "knowing points" and in terms of "putting on its long pants" and in engineering what all other successful groups have had to develop in order to attain the sound business footing that will insure financial success.

Among other things, this year 1932 has seen several important moves toward consolidation and sounder financing, and it is entirely probable that 1933 will see further constructive action along these lines.

The aviation industry has decreased, through more or less bitter experience, that while its production methods may follow very closely those laid down by the successful automobile manufacturers, its income must be derived from methods more closely approximating those by the railroad and shipping organizations.

There will be a good many more airplanes sold in 1933 than there were in the past year. One reason for this is the fact that flying schools will turn out nearly twice as many pilots in the coming year as were graduated in 1932, all of whom will be potential buyers or will fly for some private owner or transport line. Another reason is the fact that the general public is becoming air-minded, which will aid the market for aircraft as well as the organized transport lines in passenger service.

A well organized sales department should eliminate the so-called lost sales for the factories. This has been the most neglected phase of the industry due to the fact that after Col. Lindbergh's famous flight in the "Spirit of St. Louis" sales for commercial production and no well planned sales program was needed.

The Detroit Automobile Corporation, like all other large aircraft manufacturers, is constantly striving to improve its products, and has a large staff of engineers engaged in this work. Models will be changed from time to time as new improvements are discovered and thoroughly tested. New former refinements will appear, so the public is demanding luxury and finish as well as performance in airplanes.

And, just as General Motors is demanding closed automobiles as well they demand closed airplanes, and I believe that 1933 will see more of the closed types of ships sold than ever before. Of course the open ship will always remain as close as a training plane, and the ship of the type of the Lockheed Sirius that we built for Col. Lindbergh

will always find a buyer in the sportsman, as well as the military flying field.

Through the medium of education, the public is gaining confidence in the efficiency and safety of aircraft. I firmly believe that nothing can prevent, any long delay, the ultimate success of the industry.

Conservation and Lower Landing Speeds

By TEMPLE N. JOYCE

Vice-President in Charge of Sales,
Boeing Toys Aircraft Corp.

TO FURTHER with any reasonable degree of accuracy the trend of the aviation industry is almost an impossibility at this time. With the new influence of two major factors, the stock market decline and the general breaking down of the whole over-developed commercial picture, the industry finds itself with delicate suspense throughout the country flooding the already over-produced market with their surplus planes; many discontinued, young student pilots who need find the necessary jobs, and the general public, fed up on the enormous amount of publicity and unsavory crashes in all phases of operation.

I cannot too freely express the opinion that the industry has got to come down to earth. Everyone cannot fly, and the majority of our people will not want to even to passengers for some time to come, and until order planes are built. Aviation is not only more dangerous than other methods of transportation, as increases in speeds in the past have always brought about added risks. During the past year the air has had more than its share.

Why? Because aviation elicits public fancy, particularly that of the purchasers of automobiles, and larger sums of money were made available than the competent aviation executives could take care of. An influx into the industry of personnel who knew nothing of air operations resulted, and in addition many vision my young pilots were suddenly expected to assume and carry out the duties of conservative management. It is quite natural, with this state of affairs, that the industry should find itself as it is today. It would be better to let the industry shrink within itself during the coming year, and let the demand exceed the supply, rather than repeat what we have just passed through. Building upon delicate commitments from distributors and dealers, in place of solid facts, would tend to curb over-production.

The art in advancing our rapidly, and the demand is low, is to get something like production. These two factors will undoubtedly increase prices and will further cut down demand. Let us not be carried away by the rosy picture of the automobile industry, too often we draw an analogy between the automobile and the airplane.

The growth of aviation may be better likened to the motor boat and shipbuilding industry, where private activity is on the increase, and the biggest order book places during the coming year should be in the private-owner class. Accidents caused by bad weather should be less in private activity, due to the lack of that impulse to push through which has been the cause of numerous air transport

E. K. EVANS

F. R. RENTSCHELER

T. N. JOYCE

crashes. Lower landing speeds present in this class of planes, but should be still further cut down in order to reduce the bad influence of recent accidents.

There are two major areas that will bring about better conditions, particularly in private flying. First, the proper training of personnel to use these lands in avoiding trouble rather than to depend upon clever handling at the stick when it overloads them. The section of the Department of Commerce in raising schools will probably be of the greatest influence towards bringing about a proper training of personnel.

Second, reduction in landing speeds in all classes of aircraft. It appears to the writer that we have gone crazy over top speeds which, in the absence of any new aerodynamic developments, naturally bring high landing speeds. Our airports, with few exceptions, are too small and our landing speeds too high. We persist in doing one year to the probable serious consequences of motor failure just after take-off when beyond the safe landing limits of the airport, and pray to God that this unfortunate may not overtake us. This military pilot's psychology must be eliminated from commercial aviation. Railroad operation under similar conditions would be in a probable state of affairs. One is sure that the railroads do not run their trains on the hope that the maximum critical condition may not occur. To make an aircraft land at 60 or 70 m.p.h. is only courting disaster, particularly when it is expected to put this type of plane in the hands of the average man. Operators who concentrate such landing speeds in air transport operations, and designs who lay jobs out, should be introduced to a few forced landings, either just after take-off or over undesirable territory. They might modify some of their condenser sub-assembly.

The success of the Carrier Transport in winning the Guggenheim competition is a great credit to this company, particularly with regard to cutting down landing speed, and is a fine example that should be emulated by the other manufacturers in this country.

To fly is to use our wings instead of the engine. Let us have more wings.

Making Flying Simple—Selling the Idea to the Public

By ROBERT E. LEES
Staff Manager, Ford Aircraft Co.

A YEAR AGO TODAY, our outlook toward 1935 was much the same as it is now toward 1936. At that time we found the problem of selling a much higher priced airplane than its previous price, and it further will be recalled that the pessimism attitude of 1933 had also shown a decided falling off in retail business.

We find that we are in a better position this year due to the fact that stocks of new Waco airplanes here at the factory and in the hands of distributors and dealers are much lower than they were a year ago today. It is true that we will have to sell airplanes this year, but the first thing that we will have to sell the public is that flying is reasonably safe and reasonably easy. The rest will follow.

We expect our 1936 sales to exceed 1935, owing to the availability of good new production models at lower prices.

1. This industry still seems to be a seasonal one, al-

though, of course, export selling in the southern hemisphere will help balance it as will the production and development of airplanes that can be flown with pleasure in the winter time.

4. As clearly as we are able to determine, about half of the Waco airplanes sold in 1935 went into the hands of private owners, and this market will continue with reasonable stability as far as we prove to it that flying is inexpensive, safe and easy. In this connection, it must be remembered that many operators and pilots have been trained to make their living through the sale of passenger rides and student instruction, and success in this effort makes it necessary to praise to the public that flying is expensive, very difficult and thrillingly dangerous. This puts the average retail sales dealer and operator on both sides of the fence at the same time, but the ones who have specialized in airplane sales are beginning to discover which side is the most profitable, and have found that the public is very much delighted to learn that flying is reasonably economical, safe and that the average human being can learn to fly in reasonably fair weather.

5. We favor the three-seater for the reason that it can be sold at a price very little higher than a two-seater and that it has an all-around commercial and resale value.

Effect of Mergers—Adapting to Some Hard Facts—Need for Lower Transport Costs

By SHEPHERD M. FAIRCHILD
President, Fairchild Aircraft Corp.

THERE IS NO DOUBT that great industrial advance is going to be made in airplane design in 1936 and the years thereafter. The possibilities of truly scientific engineering have never been fully used. Such scientific engineering requires expensive wind tunnels, model basins and large engineering staffs, which can only be justified by organizations with large production and capital to do the research and pay for it before returns on this money are obtained from the sale of the improved airplanes. This would indicate that airplane production would be concentrated in a few of the larger groups.

In contrast to the situation in the automobile industry, there is no such thing as an assembled airplane. Most of the small automobile manufacturers depend on almost exclusively on assembly of their products. No such condition exists in the airplane industry to do and the small manufacturer. It must be said, however, that performance is not the only requirement for space and cheap planes, and it is these classes we will have the independent manufacturer.

Probably the biggest general change in the industry for 1936 will be the tendency for the large manufacturers to market the airplane and the motor as a whole. This means that airplane motor manufacturers who are also airplane manufacturers will be unable to sell their motors independently, providing the independent can buy motors as good, or almost as good, from independent motor manufacturers. This situation is a natural one.

At the present time, independent motor manufacturers

M. E. Fairchild

cannot supply motors of all sizes. However, it is only reasonable that the independent manufacturer will prefer not to build up a competitor's business through the purchase of his motors. All of these facts tend to show that at least 75 per cent of the airplane production of this country will be concentrated in the five or six larger groups. Sales and production will undoubtedly be placed on a more scientific basis. There are at present altogether too many dollars of capital used for one dollar of sales, and if any real earnings are to be made this condition will have to be reversed.

2. Aircraft production for 1936 is fixed with the airlines that there are from 1,000 to 1,500 planes which have never reached the ultimate customer. Although they are not all listed in the manufacturers' inventories, they have been sold to allied organizations and have not yet reached a user. In addition to this, another thousand airplanes were purchased by organizations which have no real use for them and are now lying in a lot, and they will undoubtedly come back on the market. I refer to transport organizations who are now finding out that they cannot make any money out of air passenger transport. We are, therefore, standing 1936 with 2,500 airplanes to get out of the way before we can start. Aviation is a luxury and with present business conditions in the country, and with people having less time to play, I see no reason why there should be a sizable demand for airplanes. Therefore, I feel the total demand will be around 2,000 planes, of which 2,500 have been produced, so that we may expect to build from 4,000 to 5,000 new airplanes.

3. If there is any one item which is needed in the airplane industry it is an annual increase of sales by 50 per cent. A forecast by the industry will show production and inventories to be kept in much better relationship than in the past.

4. There is a great deal of misconception about the use and possibilities of the airplane, much of it due to over-enthusiastic advertising on the part of the aviation manufacturers. Business houses are now finding out that they cannot probably equip all of their subsidiaries with airplanes and that getting there by airplane does not get them the order while their competitor is crawling on the train. In the same way regularity and comfort of air passenger travel does not compare with the gliding state-ments in the advertisements. Business houses will undoubtedly use airplanes and these will undoubtedly be air passenger lines. However, I do not feel that new uses for airplanes will result for any great increase in demand. Many business houses and airplanes because of their size, and the numerous subsidiary which they controlled really paid the cost of the plane. As airplanes are no more a novelty, this publicity is falling off and it will, therefore, be more difficult to get advertising managers to charge the cost of planes into their budgets.

The largest problem which faces the industry in 1936 is the question of some outside support for the air transportation lines. There is no question in the mind of any air transportation executive who has made any real study of the proposition, that he cannot depend on more than 50 per cent loads and that he is lucky if he obtains that average. Under these conditions air transportation costs from \$1.50 to \$2.50 per passenger mile, and it is being sold for from 9.5 to 12.5 per passenger mile. If some outside help is not brought in to make up this deficit, air designed for airline will probably fail, and the public generally will become disgusted with the aviation industry. Large air-

lines, intensity of service and aerodynamic improvements will undoubtedly reduce the cost of air transportation, but all of these things together cannot possibly offset these costs over 25 to 30 per cent in the next two years and, therefore, the only solution lies in finding some way to raise the income.

5. It is difficult to predict the trends in design. There is a tendency toward monoplane, especially in the light field. There is also a strong tendency toward rubber engines, and a survey of the market indicates that the aviation public is sold on and will welcome in-line engines. When it is said and seen there is little money to be made out of the partly solid plane and, therefore, a three-passenger plane has better chances for making money on the side when not being used for school instruction than the two-place and there will be a demand for it.

Let Markets Control Production—More and Better Statistics

By B. G. LEIGHTON

Is Clear of Military Service; is Right Aircraft Corp.

IT IS A COMMON LOGIC, perhaps, to say that the trend of the industry is definitely and inevitably toward merging into larger units, but the various factors which have been in existence in the past, with a rapid working out of the less efficient or too strongly financed manufacturers. With the great excess of producing capacity over possible maintenance demand we have a highly competitive industry, with all producing organizations looking strongly for the lowest costs and operations, and an extremely narrow margin of profit or a definite loss. Those who are not very strongly financed will find the business very hard indeed.

The sales force is becoming and will become increasingly important, and must inevitably take a position of predominant importance. This is to say, the selling organizations must stand in relation to engineering and manufacturing organizations, not as a force to add what the engineering and manufacturing forces choose to build, but as an agent which will direct the activities of the engineering departments and dictate production schedules to the manufacturing departments.

There are not at all pessimistic and steady growth in the use and sale of aircraft over 1936, of course. There is every indication of a normal continuation of that growth in 1936. I should place the probable market for 1936 at between 8,000 and 9,000 commercial airplanes of all classes.

The "slump" of the last year, of course, partly a normal seasonal phenomenon but it has been greatly accentuated by numerous other factors such as: (1) The die-hard spirit of many manufacturers who refused to believe that their actual market estimates had been far too optimistic and who continued building in the face of mounting surplus and then had to shut down their plants; (2) Forewarning of numerous new aircraft designs being sprung and early summer which gave an artificial stimulus

B. G. Leighton

to sales in the early part of the year followed by a rather abrupt cessation as realization came that the public is almost ready to wait to get that early estimate led operators to expect. (3) The stock market recovery. (4) A general dissolving of the non-needed planes that were so generally sold early in the year to look at all others pertaining to economics and a general pausing to take stock, etc.

I doubt if there will be a very great demand for part replacements during the coming year. Many operators are already overstocking on flying equipment. Few of these have as yet actually seen out the new equipment which has been brought on the part year.

I look for a steady increase in sales throughout the spring and summer with a recession about October, but not early as in past in proportion as has been the recession of the fall.

3. The foreign market is of course always a strong factor in smoothing out seasonal variations, but of even more importance is the development of accurate statistical information as to what actually is going on. The absence of accurate statistical study of production and actual sales in various types and in the various power and price classes is the greatest handicap of the industry today. The Aeronautical Chamber of Commerce has a real mission to perform along this line.

4. I do not look for any very great market swing true private owners in 1959. I believe that expansion will be greatest during this year in the "executive transportation" class. Service facilities and salesmanship have not yet progressed sufficiently and types and prices have not yet become sufficiently established to offer great encouragement to the true private owner. There will undoubtedly be an increase in the private owner class but it will be principally confined to the luxury or sporting class. The general outlook of the prospective private owner is still largely to "wait and see."

5. In passenger transport there will be experienced one of much larger and more types but as very great market. I expect to see a rather wide spread adoption of smaller six and eight place single engine types—based principally by motives of economy and efficiency in the theory that most frequent schedule with smaller planes will not longer volume and greater economy.

In executive transportation the four or six place single-engine cabin configuration of moderate cost seems to occupy the favored position, because of the moderate cost and depreciation ratio. I can't hold out a great future in my view for the open two and three seat arrangements except for the executive and purely sport flying types, because all new low equipment and low life, but for say great length of time in alliance without human contact. The open three seater is an improvement on the two seater in this regard but will never be considerable volume only so long as it is directly cheaper than the cabin type.

There is little question that the cabin type will steadily reach up and eventually largely replace the open cockpit type. Reasons: (1) Less noise and vibration. (2) Greater comfort—better for water, absence of helmet and goggles, no special dress required etc. (3) Greater comfort—conversion possible into solo-by solo seating arrangement.

There is undoubtedly a good market for the two-seater "cherry" cabin type because of its low price, but there will be an inevitable trend toward the four-place cabin type of about 200 hp—for the same reason that the five-

place closed cabin is so popular in the automobile market. In engines, I believe, we will stick to air cooling, because of decreased complications, but will trend toward inverted V or in some cases in the larger power classes because of demand for higher speeds, better visibility and smoother operation.

Cultivate the Easiest Markets First— Good Replacement Demand— Seasonal Problems

By WM. D. ROBERTSON

Principal Curtiss-Robinson Airplane Mfg. Co.

THE MOST important question that is before us now is that of sales. Factors have caught up with the demand and have overproduced. Therefore, it has been an easy matter to sell an airplane as the demand was greater than the supply, now it is not such an easy matter. Airplane will have to be marketed in a manner similar to that of the automobile. The factories are rapidly realizing this and are establishing their distribution and dealers in the territory, who are either owners of flying schools, two lines, and established aviation operators, or are automobile distributors who are starting an aviation department.

I have made an extensive study of the general market and have broken it down into three groups, each of which must be approached in an entirely different manner so the information that would be of interest to one group would not be of particular concern to the others. These groups have in their importance are: Group 1. Those who are not interested or connected in work with the aeronautical industry, namely 38,000 students in training, some 8,000 licensed pilots, some 12,000 licensed mechanics, and the airline and airline operators. I believe that this group is the immediate market. This group is already somewhat well interested in the technical side, as its members know the difference between tail slot, top speed, cruising and landing speed as well as other performance data, particularly the cost.

Group 2. Next in importance are the business houses. There are hundreds of thousands of companies and business establishments that would be more than willing to use an airplane in their business if they could be convinced of the actual economy of the airplane through demonstration. If they can increase their sales, and incidentally their prestige by employing the airplane, they will follow. Even before they do, many business houses would use the airplane if they could be convinced that it would be of real service to them. This can only be done through demonstrations.

Group 3. Those gentlemen who have plenty of money and fly only for the sport of it, members of exclusive clubs including the yacht club through the country who are lovers of outdoor sports.

I prepared magazine sales letters which I used some months ago in reaching each of the above groups.

Answering your question outlined in your letter, I am pleased to advise my views on the subjects contained in each section as follows:

I believe that the probable trend of the industry for the coming year will be towards further consolidation, merging of executive, engineering and factory management personnel and elimination of unnecessary

expense wherever possible. It is my hope that the coming year will bring about such mergers, consolidations and eliminations as are necessary to put the industry on a safe financial and industrial footing as that is growth because of demand for higher speeds, better visibility and smoother operation.

The expansion of 1958 and 1959 have proved that there are too many aircraft companies organized and operated on a limited capital, and during the seasonal depression these companies naturally will go out of business, leaving different types of airplanes in storage throughout the country which will have to be thrown on the market at any price, reflecting on the entire market adversely.

2. As to the number of planes and engines that will be built during 1959, it is impossible to give any exact figure, as each person's guess is in good or bad order. I do believe, however, that there will be approximately 75 per cent replacement demand during 1959 due to the fact that the new models coming on the market will be of such marked improvement in performance and economical operation that these features cannot be overlooked by the operators. My belief is that we can look forward to a demand possibly as great as we found in 1957.

3. The problem of keeping production and sales in the proper relationship is one of great concern to us, possibly because I am on both sides of the fence, namely as president of the Curtiss-Robinson Airplane Manufacturing Co. and as president of the Curtiss-Wright Sales Corporation, managing Mr. Beech in the sale not only of the products of that factory, but the products of the other factories in the Curtiss-Wright group. I find that this is the problem of the hour.

Surely we cannot expect a distributor or dealer who has not put any money out of the distributor ship of airplanes to sign a contract and live up to that contract by taking ships from the factory during the dull season in order that the factory may be kept running as a regular schedule.

Of course the ideal situation would be to have the factories run and schedule the year round and the distributor take the ships from the factory as they are manufactured. The past years have proven to us that this cannot be done and it seems to me therefore that the problem is that of the factories, at least for the present. There are two alternatives, I believe, and it is that slows the factories during the seasonal slump and open again in the spring, and the second is for the factories to manufacture the least number of airplanes in order to keep the wheels going and stock the ships until the demand opens again in the spring. Both of these alternatives have their advantages. If the factories shut down there is a certain amount of overhead and other expense that goes on just the same, on the other hand it would be wise to continue manufacturing one or two types and fill the warehouses with these two types only to have them for sale during the new models which are placed on the market in the spring. We are going that problem serious consideration and hope that the solution is not far distant.

4. I believe I have already answered these questions.

5. I believe the trend of the types of airplanes is toward the cabin type for business houses and private owners, and open types for training ships and aerial sports. The special ship for aerial sports is a very important item. I believe that the two-seater open cockpit plane will always be in demand as a training ship and that the three-seater open cockpit plane will not be in

use as heretofore as it will be replaced by the cabin plane for short passenger hops, and that four-seater cabin planes will have a very ready market in 1959. I believe also that the six-, seven-, and eight-place ships that are on the market now, mostly two-seater, and even built on original solid and question, which will result in the appearance of a popular proved two-seater cabin plane.

More Intelligent Merchandising— Effect of Insurance Costs

By R. F. CASTLE

President Coast Cities Aircraft Corp.

IT APPEARS TO ME that the trend toward consolidation in the aircraft industry will continue. At this time it is obvious that consolidation with strong companies is the only thing which will save many of the smaller companies from total extinction.

Undoubtedly, the administration of aircraft corporations in 1950 will be more economical than it was in the early part of 1958, when companies were long in cash and short in inventory. It is quite probable that the reverse of the latter situation is now true and that management is proving how difficult it is to maintain a liquid position and, therefore, how necessary it is to eliminate every expenditure which is not vital to the efficiency of the organization.

Competition for government orders will be very severe because of the fact that much commercial business which was absorbed by manufacturers has failed to materialize. In order to keep their factories moving they are looking to government orders. Production for 1959 should be about the same as in 1957 and I feel that at the end of 1960 the story will show that inventories have been greatly reduced and that the companies in the industry are as a whole in a much more liquid position than they are today.

It is apparent to me that the outstanding characteristic of 1959 will be the failure of the aircraft industry to adjust its market and to plan a real merchandising program. Undoubtedly in 1958 sound merchandising principles will be applied. The commercial market for aircraft, while not large, is adequate for the production facilities of the industry at the present time. However, the market is one which is difficult to develop and the confidence of sales is not factor which should be reckoned with in price fixing for the 1959 calendar year. Examining the price of aircraft one cannot help but feel that there has been a failure on the part of the industry to properly evaluate the cost of engineering, administration, and sales. Otherwise, the prices which have been fixed by certain companies must reflect a determination to take substantial losses on initial production.

The gradual expansion of the export field, particularly in Latin America, has been very marked during the past year, and it is my opinion that there will be continued progress in this direction. The aircraft manufacturers have a logical advantage in this field. They are in a position properly for sales they should develop a very interesting outlet for their surplus in the years to come.

R. F. Castle

The financing of sales, both for export and in the domestic field, on the time payment plan will make progress during the coming year for it is now a feature of the economies of this country and in foreign countries where American motor cars are sold. The aircraft industry must not attempt to overlook this factor.

One of the greatest deterrents to sales is the high cost of insurance and it would seem that the Aeronautical Chamber of Commerce could not devote itself to any more constructive work than that of determining sound means of reducing the cost of insurance to individual users and to companies.

Sales to private owners should depend of the experience in England is any interest in England it is worth to try and it would appear that through the medium of the Aviation Camera Club in this country the sportsman pilot is rapidly becoming an owner of a plane and time among which can be through the use of his own plane.

I feel that for the sportsman pilot the open cockpit type will remain the primary place of future. However for business and family use we can see that the cabin plane with a minimum of four passengers including pilot will be greater and greater in use. The two-place open cockpit plane will continue to popularize the three-place open cockpit plane as the latter have necessarily be out of the light plane class which means greater horsepower and therefore, higher maintenance cost.

1959 will be a year of elimination of the smaller aircraft company, maintenance of sales volume as compared to 1958 reduction of operating costs, expansion of the export market, improvement in design of plane for the individual owner and a larger use of the smaller type of cabin plane.

Export Development and Accident Prevention

By PAUL BECKER

Assistant Chief, Light Aircraft

IT IS ONE THING TO SAY THAT 1958 satisfactory progress will be made by the industry as a whole. It is not believed that any radical changes will be made in design and production, but that the usual progress and improvement will be made in these factors of the industry. We believe that the sales for 1959 will show what entered these for 1958 has not entered the production for next expansion of sales which are coming through some sources. We still believe that the industry progress is important and will remain the background of the industry.

2. We believe that 1959 production will remain on an even keel. We feel that 1959 will be a year of consolidation and expansion of the industry. In other words, that it will result in a survival of the stronger groups and the dropping out of the innumerable companies which have sprung up in the last few years, a great many of these without proper financial backing or a product which merited continuation.

3. Production and sales for the year can be kept in proper relationship with the demand and conservative survey of probable sales and the elimination of over expansion in production. Each company should produce only such ships as it has a certainty of selling within a reasonable period.

4. New markets for aircraft must be opened up over

right. However, we believe that a real field for American aircraft is offered in the export market, and that substantial increases in sales can be made in this field by proper coverage and intensive effort.

5. We do not see yet an accurate picture of the future as to the general type of aircraft which will be predominant. We feel there is a field for both the open and cabin type plane. However, in the back of our minds remains the idea that the real future of the aircraft industry is in rapid transportation of goods and passengers.

We feel that during the year a real effort must be made in all connected with the industry to build up public confidence. The recent numerous accidents have undoubtedly destroyed a good deal of the interest which had been made along these lines. Actually it seems to indicate that the greater portion of accidents are due to the personal factor, namely, carelessness, carelessness, carelessness and inadequate training. We believe that a great deal can be done within the industry itself to eliminate this factor and that the day of the so-called "careless aviator" is just.

Research, Light Planes, and the South American Market

By WM. B. STOUT

President, West Wind Aviation Co.

ON THE PROSPECT FOR 1959 in this 1959, I believe, we will be largely a question of making best with present day planes and equipment and looking up what market we can while all this are we are continuing several research to develop types which will fit the market instead of trying to force the market to take the type not suited to its needs. The field for present day airplanes is comparatively small. The field for future designs will be positively unlimited. Those firms who prosper most will carry on the most constructive research. Sales for 1959 should surpass sales for 1958.

1. Production will surpass the number of planes already on hand if my guess is worth anything by about 10 per cent. The total number of planes that were sold last year. Replacement demand during 1959 will be comparatively small.

2. Production and sales will be kept in proper relationship by designing a plane that can be safely sold during the entire year. As long as the use of the plane is seasonal, sales will be seasonal.

3. New markets are available in small super gliders for the flying of fledglings who are not quite up to piloting big ships, but who have passed the glider stage. Markets for present day planes are available only where these types fit conditions. It would be a mistake to sell our present type ships to foreign countries or any countries unless they are suited to the topography, psychology and requirements of these countries. I am thinking particularly of South America as the greatest future airplane market. The expansion of sales among that private owners depends entirely on accurate developing

Wm. B. Stout

a plane suitable for the private owner in which he can fly home after five hour's activities.

5. Radical air-cooled engines will continue in those of up to 300 hp. from those and beyond we will see the coming of water-cooled or gas-turbine engines, diesel and fuel cell power plants for large planes. For the private owner, the small radial engine of 100-150 hp. will continue in favor. The water-cooled engine is definitely an exception in large sizes.

Regarding the two- and three-seater, a two-seater plane is only a training plane. The most popular type will be the plane capable of carrying two and baggage and the best fuel for the possibility of making it a three-seater remote engine for shorter trips.

Open and cabin plane will both continue, but for all-the-year-around work, closed heated cabins are lighter, faster and more comfortable than a full-sized flying suit with all its weight and cost and discomforts. A private owner will demand side-by-side seating.

In the matter of these things, the public is the group to be listened to and not the pilots. Our problem is to give the public the thing it wants.

Learn from Automobile History

By WALDO D. WATERMAN

San Jose, San Francisco Chronicle Staff

ABOUT TWO YEARS AGO the few commercial aircraft manufacturers found that no matter what they built, if a few, there was a longer waiting at their factory door for the product. This condition caused some of new aircraft manufacturing organizations to spring into being, mainly making towards the production of more airplanes. The facts that they would fly have a reasonable performance, and were not so much totally unsafe seemed to be the prime requirements, but little thought was given to the question of who was going to purchase the large number of planes which were suddenly produced, or what their future requirements would be. It was generally believed that the average man of above moderate means would purchase these planes in large quantities.

He has not done so with the result that we now find some of aircraft manufacturing companies loaded with overproduction and with their expenditures which they move to develop rapidly, suddenly found to have no demand, and we find our infant industry with a serious case of "rickets."

Many are of the opinion that little constructive marketing effort has been expended, and that the industry's only method of obtaining this coming year is for educational and merchandising campaigns to sell its product. It is true that such efforts may bring some results—as with high pressure salesmanship methods silk garments can be sold to Tokyo—but it is obvious that the silk pajama industry would soon perish if dependent upon the Ekimono trade.

Many times the aircraft industry has been compared to the automobile industry of twenty years ago. This seemingly little comparison is obviously to many in our industry, although there have been hundreds of instances in which automobile history has repeated itself in aviation.

Twenty years ago there were scores of small automobile factories building automobiles which "put out"

A trip of one hundred miles or more was a great adventure unless the driver was something of a technical and practical expert. Also this was Henry Ford, who had been building automobiles in a small way along with the rest of them, took the same old parts that everybody had been used to build automobiles and turned them around in a different way, producing the famous Model "T" Ford which was sold in large numbers, sold, and required only low judgment on the part of the driver to successfully operate it. The price of the first Model "T" Ford was not appreciably lower than other automobiles of similar size and horsepower but it immediately supplied a demand for an automobile which could be successfully and economically operated by inexperienced drivers. The result was that this car immediately came into popular demand with a resulting increase in production and a corresponding drop in price.

The production of Ford cars grew like a snowball and production increased rapidly descended to a level never before contemplated. The whole country immediately became "awake and moved," and through the medium of the Ford car the present generation has been educated to the automobile. This education has grown upon the public and has been developed to a point in recent years where the public no longer needs an automobile as first-class as the original Model "T" Ford, with the result that the famous last year's automobile and the new model purchased as few away features which were not unknown twenty years ago yet have little appeal to the more advanced motorist.

Aircraft designers can well take this example as a lesson. Experienced pilots and people who can afford to have planes have produced our present type of aircraft to the limit. We must now build airplanes that are more flexible more foolproof, and that require less judgment and experience than our present types before we can expect the volume of sales which can only be brought about by the existence of an airplane by the average man.

Lower Prices and Year-Round Flying

By C. V. CERRINA

President, Coast Glider Co.

IN ANSWER to the probable trend of business for the coming year I have a feeling that the cheaper planes will find the more ready sale due to the fact that all of us are feeling the pinch of money and are watching expenditures more closely than heretofore. However, I feel that transportation business will be far more larger ships. In any season there will be two classes—one in the smaller and cheap class and one in the larger, even larger than perhaps any now being built, which will be used in demand.

My experience with 1958 is no more did differ from many others in that money was free and business was, in fact too easy for the good of the industry, which I think is to blame for the temporary slackening up of our forward program. I feel sure that everything is going to be all right and the approximate magnitude of aircraft production for 1959 should be as great as last year. 3. Do not look for a few changes, but rather a slow conservative re-evaluation of the program conditions which we have just passed, which will only be brought about by those who have determination and foresight to get down to business and benefit the aviation industry as all good aviation business is being handled

In other words, I feel that in order to accomplish what was done last year, all that is to be done is to put forth our best efforts toward better business methods and constructive action.

I feel that the aircraft industry can be blessed somewhat to the automobile industry—that we have reached a stage where there will be quite a number of trade-in sales for those making better deals. One of the important considerations in the aircraft industry is order that we may have an all-year-round business in order to arrange for more comfort for winter flying. This can be done through the use of cabin planes, paying particular attention to the seats, ventilation heating and light, and the traveling public, will expect these in airplanes in the way of convenience and comfort as they are used in automobiles, which at one time were unsuitable vehicles very much the same as planes are today. The problem is very simple—what worked with the automobile will work with the plane, and that is convenience and comfort for all-year flying.

Use airport facilities for servicing and shelter will have in small part in bringing the all-year show. All-year service will, of course, contribute greatly to the healthy condition of the aircraft manufacturing industry. There can be much done in the way of developing new markets in foreign countries, in which we have heretofore paid too little attention, but I am quite sure many well-known aircraft factories are looking in foreign trade at this time and will no doubt meet with much success if they follow an energetic program.

There will be in the future, large quantities of airplanes sold to private owners, and in various businesses such as the oil industry. Competition in the transportation will be forced to follow suit as the case in the automobile industry, where those using horse vehicles were forced in time through the spreading use of all business brought about by the automobile. Competition will make business accept the airplane in the same way.

As before stated, the most popular class of airplane will be the small business class, planes for private use, and large transport planes for commercial use. There will not be much field for those in between. I believe this to the automobile industry, where demand is often for a small private car or a very large bus. My conception of the popular ship will be the two or four place class for they really fit in very conveniently for all business purposes.

The use order makes feature of course, in speed, for after all that is the only reason for flying.

Steady Progress Anticipated, but Many Companies Will Disappear

By E. E. PORTERFIELD, JR.
President, American Eagle Aircraft Corp.

THE PROBABILE TREND of the industry for the coming year, I feel certain, will be an improvement in the manufacturing business, particularly in subassembly, small planes, adaptable for student training and passenger carrying. Another type, which I believe will show a large gain during 1932 is the cabin monoplane from four to eight place. In 1931, I believe there were more students trained than in any two previous years. I can see no reason why 1932 should not show as much gain over 1929 as did 1929 over 1928.

To the best of my knowledge, there are 212 aircraft factories, including those who are starting and hoping to get into production. Of the 212 now in the field, probably 30 will live through 1932. This should make a healthy condition for those which remain, as the manufacturer making eight or ten to twelve planes a year will doubtless step out of the way to make room for a better business for the factories which have adequate sales and engineering forces. A complete engineering force naturally is the successful foundation for an aircraft factory, and the sales force and distributing organization represent the superstructure. Both are very necessary, and without them, in my opinion, a factory can get nowhere.

Meepers should take place in a wholesale manner during the late winter, spring, and early summer. Some of the weaker factories have good ideas and designs which can be worked into a good factory and had considerable strength to stronger brethren.

A Detailed Analysis of Probable Sales

By R. B. SNOWDEN, JR.
President, Command Air Inc.

THAT is very little startling news in the industry for the manufacturers in the next year's developments. However, there are many refinements and new developments for improving the quality and reliability of our present-day airplanes. Taking the matter from the standpoint of one who is interested only in the production of relatively cheaper priced airplanes, I have recently made a very careful study of the probable production and possible outlets for ships priced at \$50,000 and under. I have taken into consideration the number of factories in last year's production run, the facilities of each, their probable most successful model, around which they will center their efforts, and in each case I have given credit value in the line of the current developments of the past year, the innovations carried over, the premiums of each company, its financial strength and the position that it now holds in the industry. The aim stands here to believe that an effort will be found for approximately 4,700 new airplanes at the price of under \$50,000 (see table next page).

I feel naturally that most of the carry-over 1,700 ship work or new and hand planes will be sold at prices under \$30,000 and the fact makes me feel that Group 1 in the following table will be the smallest group in the first four. I have served at seven main groups and each factory, by virtue of the price of its product, is put in one or more groups. Then I have given an A-B-C rating to each factory depending upon its facilities for production and price. I have made what I feel is ample allowance for new price reductions, which we all feel will be inevitable in the industry. As for outlets, I feel confident that the many airplanes will not only be built, but readily sold. Undoubtedly the domestic and export markets will be enlarged. The first year's production will overcome the present gloom with which we are all unkind. The

R. B. Snowden, Jr.

flying schools must have replacements, part owners will want something a little better, and the new graduates must be served in their desire to fly. There will be streamers, price reductions, and, probably, a few bankruptcies, and these bankruptcies will be greatly postponed upon by many of those who were smart enough last year to stand off and watch the show go on awaiting the proper opportunity. I do not feel that the sale of these bankrupts will interfere with the new plane market. I feel only that it will enlarge the new plane market by adding new owners and new buyers to the flying personnel of the country. I cannot look toward 1930 with anything but optimism.

Group 1 (\$3,000 and under)	500
Group 2 (\$3,000-\$4,000)	1,580
Group 3 (\$4,000-\$5,000)	1,300
Group 4 (\$5,000-\$6,000)	595
Group 5 (\$6,000-\$7,000)	325
Group 6 (\$7,000-\$8,000)	182
Group 7 (\$8,000-\$9,000)	100
Total	4,762

Hope for a Good Year and for Increased Private Flying

By WALTER H. BEICH
President, Citrus Wright Sales Corp.

THE PROBABILE TREND of the industry for 1932 is, in my judgment, to be in the nature of an upward swing. In the past few years a sound foundation for the manufacturing, distribution and refinement of the airplane has been laid and in spite of the fact that we are in a boom period, indication point toward a wider public acceptance of aviation this year. Our organization has profited greatly from past experience and we feel now this opinion is well founded. We now have an engineering research division whose function is the development of advanced types. Sales trends and efficiency in production are important considerations in the development of new and there will always be Citrus-Wright planes available for each new step in the commercial operation of aircraft. I feel that commercial transport work will increase greatly during this year and that private flying will also be more popular.

I would not care to make a certain prediction as to the total production in 1932, but I do believe that there will be some increase in the new plane production over 1929. Furthermore, I believe that there will be a general strengthening of aircraft sales following the International Aircraft Exposition in February.

In order to maintain the right relationship between producer and sales, it will be necessary to analyze markets more closely, to better educate people as to the valuable uses to which airplanes may be put, and to maintain proper factory control at all times. Due to the fact that airplanes are not yet turned out quite as fast as other production commodities, I believe it will be somewhat possible to maintain more uniform production at factories, despite the seasonal nature of the business.

I do not think there is any question but that private sales will be stimulated in 1932 (though not in the proportion they might be if financial conditions were somewhat different. There are undoubtedly a large number

of people with means who will join the ranks of airplane owners when the advisability of such a step has been properly put before them.

In regard to type, there is no question but that the closed cabin plane is coming into favor more and more as people in general become interested in owning planes. In the past year the ratio of closed to open planes was about 40:60 and this year I am sure the ratio will be at least 50:50.

Moderately Increased Production—Better Co-ordination of Sales and Manufacture

By W. B. KENNEDY
President, Ames Taylor & Utter Co.

WHILE I WOULD SAY THAT to 1932 is a concrete figure the amount of business which will be done in 1932 I do think there will be a quick rebound during the coming spring, and the probable trend of the industry for the balance of the year will be steadily upward and will gradually level out at a more stable basis. I should say that on the whole the construction program of the principal commercial aviation companies during 1930 will be at least 70 per cent more than 1929. There should be a closer relation between the financial and the design, production and sales departments, this will, I think, assure a more steady production by taking into consideration the type of plane best suited to the job it is to do for the purchaser. I would say 50 per cent of the planes sold during 1929 were not right for the job, and did not operate economically, besides, the first cost was much higher than necessary.

Absorbed free capital, ample commercial credit, growing export markets and the co-operation of state, municipal and national government in granting forward expansion seems to promise an excellent maintenance of the labor and industrial markets of 1930, which will naturally reflect favorably on the aircraft industry and prevent the kind of trade recession which has recently followed a financial collapse like that of 1929.

In my opinion, aviation is passing through its first four-year reaction, and since it grew to be a recognized industry, and a great many of the smaller units have already collapsed

all plans for expansion. The other units which have been affected in 1929 for extensive construction are going forward with these plans, but perhaps on a somewhat more conservative basis. This is particularly so where most are using their personal fortunes.

Close co-operation between the manufacturer and distributor both having ample reserve capital to tide them over the dull periods which always occur in any industry, will assure steady production, but sales will always be seasonal to some extent at least. Some think by developing our foreign markets the sales would be more steady. In my opinion, we should develop our home territory to a point of greater production, making it possible to sell at more attractive prices before we enter the foreign field. By building the small two- and three-place passenger planes with low horsepower, we not only supply

W. B. Kennedy

the school with an ideal place for training students, which is economical to operate, but we also prevent the school plane for the sportsman who wishes to fly in his country estate, put out on a business basis. I think all that is needed now is such a new product and the thrust of the industry, and in a very few years we will have an industry which will surprise the most optimistic of the pioneers.

Priority to the Government Market— Plenty of Cash on Hand

By JOHN H. BAKER
President, Air-India, Inc.

THE GREAT VALUE of the business done by the aircraft industry in 1929 will be on government contracts, and with these transport lines schedule held government contracts.

Commercial sales in 1929 should be expected to be considerably less than in 1928, as fewer new companies will be organized, the large amount of new equipment delivered in 1929 will scarcely have become obsolete, and the second-hand problem is increasing with us.

Offsetting and favorable factors are the assurances of a great number of new airports and of an enlarging and increasing interest in learning to fly on the part of the younger generation.

From the manufacturer's standpoint I consider two problems paramount: (a) The use of lighter materials, resulting in more payload per horsepower; (b) Design reducing such further the risks of judgment in piloting. I see no likelihood of an extensive private buyer market until such goals are attained.

Transport companies will go after the package business. I have never understood why they did not do so prior to making passenger business. Night passenger service will have to be guaranteed.

Distribution, field service and accounting methods will be developed on a standardized basis in 1930.

The prices at which most aviation securities are now selling will tend to prevent the entrance of new competitive interests unless provided with government contracts. The industry as a whole is over-supplied with cash, and well-managed companies should not need more cash in 1930.

Emphasis in 1930 should be on laboratory research. The outlook is much better than it was a year ago.

* * *

More Speed and More Gliding— And Cheaper Engines

By J. D. ALEXANDER
President, Alexander Aircraft Co.

IT FEELS BATTERED, DISHEARTENED, the production and sale of airplanes and aerial transportation for 1930. The relation of air transport rates will undoubtedly con-

tinuous many to travel who have not been in the air. This will create more confidence in aerial service.

Probably more airplanes will be sold and used in 1930 both for business and for pleasure, but they will be mostly of the cabin type and they will have to be able to cruise faster. The exception will be the slower open ships used for training.

As in the automobile business there is a constantly growing demand for more power and speed. Future motion must be larger and better streamlined. 1930 will see the beginning of delivery for the radial type motor and the development of several six-cylinder motors.

Many things will be done by designers to reduce drag, such as cowling landing gear, reversing struts and generally cleaning up designs.

The glider movement will stimulate light training. Many men who think themselves too old to learn to fly will be drawn into gliders which they will fly with little trouble. They will then enroll in flying schools and buy airplanes. Probably before the end of the year every flying school will have six glider department for kindergarten flight training.

Motor prices are coming too high—too large a percentage of airplane cost. These prices will come down in 1930. Motor manufacturers will realize that it is a good business to go to spread their money over development costs over a longer period of time. We have proved that it is the proper thing to do regarding such costs on our airplanes.

The Slump Will Prove a Blessing— The Fittest Will Survive

By GLENN D. ANGLE
Vice-President, Air-Built Aircraft Engine Corp.

THE "GOLD RUSH" in aviation during the preceding months has been generally viewed with both amazement and alarm among those of us who have enjoyed it for one or two years in the industry. Scarcely anybody doubts the present or future possibilities of aircraft as a means of transportation, but substantial progress should be measured by engineering or airplane development and not by the amount of capital invested. The recent slump may be considered most fortunate for the industry as a whole since it has given us all an opportunity for retrospection.

We have seen new companies springing up almost daily and apparently finding little difficulty in interesting the necessary working capital. I suspect that about everyone who could build an airplane or an engine was representing a company, and planning immediate production. These infant organizations, no doubt, entertained profound hopes that they could share lucrily in this potential market, despite known difficulties and delays encountered by even the most experienced in matters of organization, finance, design, development and manufacturing, as well as in securing the required approved type certificates before sales could actually be made. A high mortality percentage among such organizations is inevitable and unfortunately results in creating a rather unfavorable reaction in the minds of the investor or prospective purchaser.

There will be few companies lowered for the misadventure of several and regardless of competition they will react with success if their product is right and they

have the ability to market it. Of the several phases in the present state of the aircraft industry, the most vital of all seems to be a vast army of employees and engineers, whose the value of capital and new companies has grown out of what in few are really ready to be sustained because of failure to solve one of many of the general problems encountered above. Over-production of designs may be quite as serious as over-production of parts and even more wasteful of capital invested.

I believe that more airplanes will be manufactured and sold during 1930 than during the preceding year, and I further believe that the largest portion of this increase will be among the two- and three-place ships. I also believe that the majority of these ships will be powered with radial air-cooled engines and that the arduous of the air-cabin engine manufacturers will have become noticeably dampened before the end of the year. The demand for a suitable replacement for schools and private use was unfilled during 1929 and will be even greater this year.

Every manufacturer must study his own particular problem and be optimistic to the proper degree. It is believed that such can be done, if possible, without a serious production for the year and avoid any sudden changes in schedule regardless of demand. Aircraft production must be sold this year, and most attention will be given to proper selling methods than at any time previous. Conservative manufacturing, honest and far-sighted advertising, prompt and efficient service, and ethical sales policies may be exercised by the companies which expect to survive. Now that the "Gold Rush" stage is over, it is time to critically regard the products and financial statistics with a view of determining which companies will withstand the expectations that usually follow a boom. This evolution will eliminate all but the fittest.

The Honeymoon Is Over— Prescription for Progress

By EDGAR S. GOFF
President, Republic Aircraft Co.

AVIATION HAS HAD, as its comparatively brief history, two broad periods of development. The development during the War expanded manufacturing facilities far beyond what the public could absorb after the cease-fire treaty was signed, and through the design of airplanes to a pre-war aviation situation, as this can be seen today, at least, was applicable only to military aircraft, as the general day commercial ship was then negligible.

The last two years have shown a tremendous expansion of public interest, followed by the steady growth of sub-conscious realization in flying which is after all, the true foundation to the success of airplane development.

The monetary reaction in all lines of business will undoubtedly be a true balm to the aeronautical industry. In the past years as prices have been bid out on a magnificent scale. Aircraft have been designed and constructed offering every element of solution to the traveling public. The various companies

have been proceeding along independent lines, each developing its own product in diverse ways. The several members of the past year will surely have their kind of airplane, and will tend to split them into a coherent whole. Opportunity will now be given to the industry to catch up with the designs and plans which they have evolved in the past two years and to prove to the general public, which after all is the ultimate customer, that their assumptions have been founded on fact.

The era of promotion has ended. We are now confronted with the need of hard work. Now the opportunities have been exhausted, we must apply ourselves to a simple task.

Prospects for \$20,000 Amphibians For Ferry Service

By ALBERT PALMER LOEWING
Vice-President, Republic Aircraft Co.

THE NEW YEAR has scarcely been before we realized that there was a market for expensive airplanes if they were able to earn money. It was also gratifying to learn that there were still a few individuals left in the United States, who despite the stock market crash, could afford the purchase of a high-priced airplane.

I feel that the sales trend for 1930 as regards to airplanes in the price class between fifteen and thirty thousand dollars, with which I am most familiar, will show a greater volume than in 1929. One phase of aviation that will cause this is the use of transport airplanes in both land and water. This is being done successfully now in two places on the west coast—Seattle and San Francisco and will without question spread to many other localities. This is an angle of the business that had until very recently been completely overlooked, and was the unexplored mine to the paying business that stood at its entrance. Moreover, it combines both features. It gives an individual a short airplane ride for a very small sum of money and yet takes him to a desired destination. The fare on the air between Seattle and Vancouver is airplane distance of 15 miles, at \$2.50 per passenger. On San Francisco Bay, three different routes are prepared. The fare here will also be \$2.50 per trip. On the Seattle to Vancouver run 14,000 passengers were carried in three months at \$2.50 per head. With such a volume of gross we can readily see that the total cost of the airplane is not the paramount consideration, as this cost is really absorbed in the great volume of traffic required.

There are, of course, many advantages to a short run in comparison with a long-distance transport route. Permanent facilities are only needed at one end of the line. The traffic which makes the business, being local, is readily caught out and returned so that it has a new form of short air transport which promises the greatest hope of expansion in the near future. The loads that pay well usually are season business or boys. This calls for an amphibious plane, and ramps at each end so this way a plane can be quickly loaded and unloaded and then turned around.

I feel that in 1930 there will also be a market for airplanes on the fifteen to thirty-thousand-dollar class by operating companies who will have their machines able for shorter. As more and more people fly and become sold on the advantages of speedy air transpor-

EDGAR S. GOFF

tion they will consider chartering a machine long before they are ready to purchase and operate one themselves. Therefore, if I consider that the main deterrent to a big chartering business has been the lack of the readiness of ground landings, and the unavailability of those facilities to the centers of population. This is rapidly being overcome and I think that beginning in the spring of 1930 a very substantial chartering business will be revived.

As regards the individual ownership of expensive planes, I believe that this business has not been properly developed, not due to any lack of initiative, or the airplane selling end, but chiefly due again to the lack of ground facilities necessary to inspire confidence. There are many men of wealth in this country who are potential purchasers of expensive airplanes but without a doubt there is need in their mind the present "hot dog" status of commercial aviation, dusty, old-time, flying fields with unreliable broken-down hangars and a general depressing atmosphere.

When some of our new fields are completed, in the spring of 1930 with modern, clean substantial hangars, well-lit fields, and runways, I feel that a new class of purchasers will enter into the airplane world.

Bringing the Public and Aviation Together

By C. S. "CASEY" JONES

President, Central Flight Flying School

THE success of aviation as an industry depends in all probability from this time forward upon the quality of the merchandising which is employed in bringing the public into the ranks of buying and repeating customers. Naturally, the quality of individual product and of the service to accompany it are both exceedingly important, but neither will be factors comparable in paying the rigidity of the industry's success in volume of business, to the able to be played by sound merchandising.

Not so very long ago, cars and women were flying for the first time in heavier-than-air craft, and this constituted the period in the industry of innovation and demonstration. With the succeeding wartime and post-war development commercially, engineering, constructive hold time, the center of the stage. Finally, after the pioneer flights in the past three or four years, promotion, financing and organization were completed.

Henceforth, the problem before the industry is generally to sell aviation to the public. Design and construction must be maintained and improved constantly and the attention is being guaranteed in the promise of healthy competition. Service must be brought to a high state of perfection and again competition makes this assured. The final test of success will remain in the balance sheet of each company, with the credits and debits depicting its sales.

Merchandising is not necessary to aviation, the most modern, vigorous and sound merchandising which it is possible to employ. Therefore, the industry is on the lookout just at present for the most authoritative information on this subject, and market surveys will probably occupy

the major portion of the industry's attention for some time to come. By the time this progress of merchandising achieves real effect, the public will be thoroughly air-minded and, in addition and which is better, air-settled.

Better Financing and More Aid to the Dealer

By R. N. WHITEHEAD

President, Whitehead Manufacturing Co.

THE manufacturer's position previously in the open cockpit type of aircraft, which only has been under attack by an and therefore studied. Reply is being made to your paragraph by accident, as follows:

The aircraft industry for 1930 is going to be in a much sounder boat than in 1929, after going through the fire of the lack of sales during the latter part of 1929 and the severe depression of Wall Street. It is my opinion that in the long run this experience will have a very fortunate stabilizing effect. It will remove many doubts of many money and bring everyone to the realization that after all the more sound business principles must be adhered to if success is to be obtained in aircraft, as in other lines of manufacture or sale.

2. From our study we estimate that the total production for 1930 will approach the same figure as 1929 but this production will be more selective and more suitable to the market demand.

3. Little more can be done than has been done in the automobile industry in order to prevent today's unsuitable conditions and following this industry, the open type planes for the Spring and the closed type for the Fall, make the natural centers of the drive.

4. In our opinion, the industry does not need new markets. It has a potential market within the United States far beyond the most pessimistic estimates of any sales manager. Few have learned how to sell airplanes to the potential market and the problem is so new that many new sales methods will have to be developed.

In the first place, convincing the individual consumer who is the ultimate buyer (who can be ultimately sold in volume for stability), must be along financial lines laid down in this country for other commodities of like value. In other words, financing to the distributor or dealer and from the distributor or dealer to the consumer must be facilitated by the large financial institutions, either of the old line, or those developed by some of the larger aviation aids. This financing must be provided at a reasonable price to include equipment. The distributor or dealer should not be required to tie up more capital in the handling of aircraft than would be recovery in the handling of automobiles, radios, washing machines, etc., in like volume. The consumer should be able to buy aircraft in the same convenient way that he purchases the several items named. A great deal still remains to be done in this matter and I believe 1930 will be the first year in which any reasonable plans will be effective.

Secondly, in the manufacture of aircraft we have substantially the first attempt to produce and sell to the public an article that cannot be shown in the showrooms windows and in general be brought to the eyes. The general potential buying public only sees a plane once in a while as a field, usually moved off for safety, and

therefore must depend on pictures in the Sunday papers for his familiarity with planes. These pictures for the most part are large planes and have no interest at all to him as a motorist. It is well known in merchandising that a man who sees a washing machine, radio, etc., in a window many, many times before he even has the urge to make inquiry in regard to it, and this visibility of the general public to familiarize themselves with the plane it class had to be one of the most difficult sales factors to overcome, but one of the most important. Real volume largely depends upon it.

The distributor or dealer is very much like Halsey Crane. He has his own airport, but ordinarily has no facilities for financing or financing in his sales efforts, that is the lack and the lack of the possible increased public contacts with the principal centers is very limited and this is particularly the case with reference to contacts with those who are able to buy planes. These distributors and dealers must be shown the way to lay down proper facilities in sales.

5. We believe that the two seater and three-seater are definite standard types that will always persist and be made and sold in volume. They may be considered as comparable to the standard or five-passenger open car on one hand and the seven-passenger open car on the other. These planes will be the backbone of the sales side of the dealer planes. The new seven-passenger, after being brought about the airport, will most likely armstrong in the same sense that the seagoing man must learn seamanship. In the many years of seamanship as a substitute or home study has taken the place of actually being in the water for a week at sea and this is close to apply in the case of aircraft in regard to armstrong.

In closing, it is my firm belief that the makers of open cockpit type planes will be much more sound and will actually make more money in 1930 than in 1929. Many finance plans will be in operation, some of which will prove properly and these plans will have a stabilizing effect and will produce a large expansion in sales. I believe every manufacturer is seriously studying this general sales problem and the aids to the distributor or dealer will be much more than were provided in 1929, with the result that these sales representatives will make much better showing individually and thus increase the volume from the manufacturer.

Closer Adoption of Types to Needs—More Seaplanes

By A. G. MEULIER

Anti Sales Manager, American Commercial Sales Corp.

THE COMING YEAR will see the hot-rod stabilization of the aircraft industry. The latest will arrive. We have seen many meaningless airplanes on the market, planes that were not serving a definite purpose, planes that did not have a marketable value. Experience has taught us what type planes are needed for student training, for private use and for air transportation lines. Only the manufacturers of planes that will fit these needs can carry on.

Production of one of the most requested items that can be watched with great interest. One certain article at a definite figure as to how many of the planes of the type the manufacturers are to be sold over a year's period, but a manufacturer can, through definite contact orders

with his established outlets (dealers and distributors), get a conservative idea as to the number he must manufacture. Over-production has been in the past, one of the greatest drawbacks to the advancement of the Aviation Industry. New markets must be created. We have all seen enough of this idea of selling such other people who do not fit more must be reached and this can only be established through proper sales presentation schemes to attract the market we are striving to reach.

It is my firm belief that in the coming year, we will see many more amphibious and flying boats being manufactured. It is true that they have made rapid advances in the construction and design of the airplane, but there has been an unreasonable neglect in the furnishing of design and construction of the amphibious and flying boat. People are looking up to the idea of using the many waterways in the United States as natural landing places.

Stronger Companies and More Private Owners

By MINTON M. WARREN

President, East Aircraft Corporation

THE PRESENT SEASON, depression confined with the stock market, should be a great help to the aircraft industry in closing down many of the weak aircraft manufacturers who were organized more for selling stock than for selling planes, and whose output is at less than manufacturing cost, resulted in over-production and distress selling in the airplane market, with resultant loss to legitimate manufacturers.

With these companies out of the picture, it is possible that the stronger and well financed companies with good products may be able to sell at a profit, and to increase in volume, and at least build their present prices.

In spite of the distress selling and over-production, I believe that more airplanes will be sold and manufactured in 1930 than in 1929, and that this will result in the large increase in airports and student pilots and replacement demand, which should be particularly large in 1930 because of the supply of obsolete models and surplus, which will be discarded. The surplus aircraft, however, will be scarce and the Aviation Credit Corporation will be able to make a factor in enabling small dealers to carry on based on one or two new planes, and in this way smooth out the production curve of the factories, which is now so seasonal.

We note an increasing demand from road private owners with at least one-third of air planes going to private owners for strictly pleasure purposes.

This in-line regime is certainly becoming more popular, especially in light planes, and the two-seater is replacing the three-seater for student training and sport use.

Although open planes will always be popular for sport and training purposes, I believe that the long range seaplane will be a leader in the automobile and to seawards sales or marketable types.

Other contributions in this symposium will appear in next week's issue.

M. M. Warren

THE Aeronautic Industry DURING

By
R. SIDNEY BOWEN, JR.
Associate Editor of AVIATION

1929

THE YEAR OF 1929 might well be regarded as the pivot point in the history of American commercial aeronautics. There are, of course, those who may lift up their voices at such a statement and proclaim that the year of 1929 will never have an equal. This is quite true if one is to judge the growth of an industry in the amount of public attention that it receives. On the other hand, if the growth of an industry is to be judged by the amount of public patronage that it receives, then the year of 1929 can truly be regarded as the pivot point in the history of commercial aviation in this country.

Public patronage in something which the aeronautic industry has not acquired as yet, at least, not to any really notable degree. And public patronage 365 days out of every year is something which the industry must acquire if it is to continue to survive and prosper. However, let it not be thought for a second that the trade desired public patronage is not forthcoming. It is, and not just sometimes in the dim future, either. In fact, we are optimistic enough to believe that it is just around the corner and that we need not our grandfathers' wit without that historic and now heartrending error. Therefore, let us not start bemoaning the crop, but rather, review the aeronautical industry's changes and losses of 1929 in order that we may obtain a clear picture of just where the industry stands today, and of what is ahead in the north of building up a steadily increasing amount of public patronage.

It is admitted that the famous flight of 1927 attracted the interest, love and admiration of the general public. They constituted the "break" for which a struggling group of pioneers had been praying. But there is no need of recording in detail the outcome of the break. It is well known history that almost overnight a dream became a realization, that all sorts of new enterprises sprang up throughout the country; that sales went sky high, and that clouds of money were poured into the aeronautical melting pot.

For almost two years the mad parade carried on, and then shortly after the beginning of 1929 it began to slow down. Sales began to drop, stock prices began to drop, and the spirit of a lot of successful men began to drop, also. However, the dropping business was unavoidable. Such unprecedented prosperity could not possibly continue in the face of so heated a market as existed

Now that plans of endeavor during the new year are being made, it might be of considerable help to review the year that has recently passed into aeronautical history. The lessons taught by experience, no matter how indelibly stamped upon memory, are often overshadowed by the passing of time, and the prospects of future accomplishment. To review the past year in detail would require volumes. Yet, on the other hand, it is possible to review the important and outstanding features of the year. Particularly those that may have an effect upon the future of aeronautics in this country. For that purpose we devote a section of this issue. The accompanying article deals with the industry as a whole during 1929, and the five other separate articles are on the subjects of airport development, air transport, trend of design, aerial engine, and aeronautical finance.

at the time. And strange as it may seem, that market was the industry itself and not the general public as many believed, or were led to believe.

In short, for two years the industry had been selling its products in itself and at the beginning of 1929 some sales were right next door to the sunburning point. It is so quite probable that had production facilities been as that new what they are today, the sales slump in the industry would have come to pass much sooner. The beginning of 1928 saw the industry far ahead of 1927 orders. The

beginning of 1929 saw the industry behind on 1928 orders. But the beginning of 1930 does not find the industry far behind on 1929 orders. In fact it finds that there are from 700 to 1200 airplanes on its shelves.

Therefore, the year of 1929 can truly be considered the pivot point in American commercial aviation, for it was in 1929 that overnight prosperity selected one and the industry took steps in cooperation to a more business-like basis and pressed forward toward increasing sales volume, and not fluctuating quick sales volume in a heated market.

THE OLD SAYING, that "what we stand and divided, we fall," was more or less the theme of the year just ended. The beginning of the year saw almost five times as many manufacturers fighting for individual existence. And of that number, at least 80 per cent were endeavoring to make the market see their product instead of making the product see the market. The sales slump that saw the ruin of many was not rather than attempt the manufacture of several types of planes, certain manufacturers and financial groups decided that there was both strength and profit in unity. As a result, mergers and consolidations took the aeronautical world by storm.

For economy's sake, it might be stated that the merger and consolidation had had its real beginning in the last of 1928. In December of that year United Aircraft and Transport Corp. was formed. The stock, however, was not issued until after the first of 1929. The second group of the present time "Big Four" is announced. . . . The Aviation Corporation . . . was announced in March of 1929, and the third group . . . was announced in June. During all this time two prominent groups, the Curtiss-Wright group and the Wright-Hey group had been operating, each, as partial units, in a number of widely varied sales enterprises, and in July the two combined to form the Curtiss-Wright Corporation, the fourth and last of the Big Four.

"The Big Four"—the four largest building companies and their subsidiary companies.

tion led the smaller, but by no means less important groups in the industry steadily started to follow suit and for a period of months the organized pattern of the industry was in the process of continual change. As has been mentioned, mergers and consolidations took the aeronautical world by storm, and regardless of the amount of benefit to be gained, some companies merged and re-merged, and consolidated and re-consolidated, until it was almost impossible to keep tabs on who was with whom and what was with whom, from one day to the next.

The benefits of the merger had to the industry as a whole can not be fully estimated at this time, as there will undoubtedly be several more changes before the smoke clears. However, a clue is taken for granted that the industry has progressed and will continue to progress as the result of 1929's mergers and consolidations. To begin with, the loss of several worthy though financially disabled companies were saved by the mergers. Had they been forced to carry on independently they would undoubtedly have sunk below the waves of oblivion as it is now. Some brains and ability have the opportunity to contribute unhindered to the progress of the industry. A second benefit is that the majority of the money invested in aeronautics has been collected together in a few groups where it will undoubtedly bring forth the best results. A third benefit is that the mergers and consolidations brought the interest and money of allied industries into aeronautics. A fourth, and undoubtedly quite important benefit, is that the mergers and consolidations will gradually force most of the existing fly-by-night and 127 are endeavors to cease operations, due to the seriousness of competition with well entrenched companies.

Let it not be believed, though, that the mergers and consolidations of 1929 were all perfect. In fact, they were far from it in many cases. One of the unavowed

regularities in circumstances today, is why some of the reorganizations merged with each other, or were bought outright under the same holding company. We put it down to the hectic drive to merge and consolidate, reorganize. In looking over the industry's line-up as it stands at present, one finds many instances of where two, and sometimes three, direct competitors of each other are grouped together. It tends to mean that many of these are white elephants who come in with the tide, and it will be interesting to note how long they will last before being split up, or washed out of the picture entirely.

From the standpoint of production facilities, 1929 was the pivot year in American aviation. Up to about the beginning of that year manufacturers were working

Above: Working plans on the buildings of the Alouette Aircraft Company at Colorado Springs, Colo. Below: The Gering City & L. plant of the Gering Airplane and Motor Co., Inc.

day and night to least production to a point where it could at least keep level with sales. To do that necessitated the construction of new plants or the enlarging on a big scale of old plants. In addition it necessitated the installation of more equipment, and, in many cases the hiring of more personnel. And in 1929 the supply-demand point was reached. Today the airplane and engine factories are equipped to turn out far more planes and engines than the present market can absorb or has absorbed since Lindbergh's flight.

In keeping with the enlarging of production facilities, production methods and factory operation have been re-

vised also. Better materials are now obtainable, better workmanship is being put into the products, and there is better material control in purchasing, in the store room and in the shop stock-room. While the trend of design during 1929 is discussed elsewhere in this issue, as a matter of record it might be stated here that production in 1929 was not characterized by marriage new features, but rather by a replacement of detail—the cleaning up of the 1928 product.

Incidentally, it takes but little thought to realize the good effect that the mergers and consolidations of 1929 had upon new production in general. Several companies are now in a position to give valuable assistance to each other, where before they were as ships that pass in the night. And perhaps of even greater importance is the opportunity

for a more efficient and satisfactory adjustment of factory personnel. Undoubtedly it will be found that the employer overflow of one plant can be most advantageously used in another. And that fact, by the way, looks true regarding the executive as well as the time-clock puncher.

Aircraft operation also turned the corner in 1929. True a number of passenger lines, and of course, mail lines, were operating daily for some time prior to 1929. But it was during 1929 that passenger traffic in this country reached a figure comparable with that of an airline in other countries. And it was in 1929 that del-

ivery lines were taken to combine air travel with the older and more established means of transportation. Perhaps the biggest boost that air travel has received since its inception was the active interest that the railroads took in the airlines. And as history shows, that interest crystallized during 1929.

However, the year of 1929 proved that air transport in this country is still far from being conducted on a profitable basis. Traffic, while bigger and better than 1928, indicated that the American traveling public has still to become accustomed. And that it is not inclined to become accustomed until flying rates, in actual dollars and cents, are within the limits of the average traveler's pocketbook. It follows that it was the experience of 1929 that brought about the drastic cut in flying rates last month.

In short, from an air transport angle, the year of 1929 was encouraging, but it really did not come up to the hopes and expectations of airline operators at least from the standpoint of passenger by the general public. Of course, from the standpoint of new lines established and flying, service and airport equipment installed, it was indeed a busy year. Perhaps some idea of the growth of American lines, domestic and foreign during 1929 can be obtained from the following:

Of the 54 domestic lines carrying passengers now established, 25 were inaugurated during the past year.

Below: A section of the Boeing Airplane Company factory at Seattle, Wash. Below: The newly completed plant of the Wright Aeronautical Corporation at Paterson, N. J.

customer upturn in mind. All of which brings us to the most important lesson that we learned during 1929—the lesson that has to do with the marketing aircraft products.

As has been mentioned at the beginning of this article, from 1927 to 1929 aircraft sales were asking sky high, but with the coming of 1929 came the realization that the industry was selling to a very limited market—a market that was the industry itself. And the result, of course, was that aircraft sales around the subscription point and that sales volume for 1929 fell far below expectations. So far below, in fact, that factory "shut-ins" are well stocked with 1929 production that must be disposed of first before the plane is close for 1930 effort.

When sales first started to slump at the beginning of the year of 1929 (the slump was felt by some in the

Fall of 1928) stock market prices began to slump also, and when the Wall Street after attack the front pages of the daily press a lot of aero-driven engines went up the flag. It is quite probable however, that regardless of the Wall Street panic, the aeronautic business would have taken place anyway. Supply far exceeded demand, and there was not nearly enough business to go round. Particularly so in view of the fact that the industry was greatly overproduced.

What there was a fitting remedy of the existing ailment? The slump was severe here, for although it was unfortunate for those concerned, it removed some of the firms from the field. The mergers and consolidations were also a help for they combined individual efforts. But the greatest remedy of all, and one that has still to show its real benefit, was the realization on the part of the industry that new markets must be developed, and the unanimous determination on the part of the industry

and entirely reiterate that the development of either market is dependent upon the reaction of persons and companies not engaged in aeronautics. That fact was the high point in the unorthodox lesson of 1929. And that fact will be the keystone of effort and progress by the industry in 1930.

At the present time there is little if any market research work being done in the aeronautic industry. The experience of 1929 will soon bring that to pass, however. The year of 1930 will be witness to a widespread reorganization of the "smoochy" selling sales organizations that went to pieces on the market rocks of 1929. In short, aircraft merchandising is a subject about which very little is known at the present time, but which will receive concentrated attention from now on.

There is a tremendous amount of work to be done before the aero industry can boast of any really profitable degree of public patronage.

Part of the task was accomplished in 1929. One item was the sinking in of the realization that outside markets must be cultivated and developed. Another item was the mergers and consolidations to better serve and serve the new markets as well as the old. Still another was the development work of the airlines as the matter of passenger convenience and comfort. Incidentally, air transport will always be an important factor in aircraft sales volume. . . no one, to our knowledge, ever purchased an airplane before he had flown one. The fourth item was the high degree of production efficiency attained during 1929. The industry need have no fear for some time to come of losing a sale through the lack of a product.

We repeat, however, that much work remains to be done. The public has yet to be sold in quantity. And that task is one which will take time to accomplish and we

need not be disappointed to see sales for 1930 fall below the 1929 mark. Fall below they probably will in total number, but, on the other hand, they may exceed the 1929 mark in total value, due to the steadily increasing amount of commercial transport work being done.

Regardless of the long hard pull that is ahead of us there is no need to fear the outcome. As a matter of fact, after the changes and lessons of 1929 the industry is in a better position for future effort than it ever has been before. In addition to past experience, which can always be regarded as an asset, it possesses a capital investment of around four hundred millions of dollars. Fifty per cent of which is available within twenty-four hours for expenditure on future development and progress.

Flights of 1929

Showing a Tendency Toward the Sound Improvement of Air Travel

By JOHN T. NEVILL.

Devotee of Aviation

and ADAM LONG

REVIEWING the achievements of the aeronautical world, it becomes forcibly apparent that no previous year has been so productive of world's records and notable flights tending toward the sound development and improvement of air travel for the general public.

An outstanding feature of the year's performance is the success of commercial manufacturers in accomplishing tests ending for large expenditures and elaborate organizations. Facilities until 1928, when, as a result of Colonel Charles A. Lindbergh's well-timed test, civil aviation found itself possessed of ample capital, such developments had been left largely to the Army and Navy. It was in 1929 that the financing provided during the previous year was effectively geared toward producing constructive results.

From the standpoint of the air

traveler the year 1929 saw the world circumnavigated by the *Brittania* and *Zeppelin* in 21 days, 7 hours and 34 minutes, with but three stops and with 61 persons, 19 of them passengers, on board, the first world flight since the Army's airplane expedition of 1924. Captain Hugo Eckener encountered none of the usual hazards which the Army surmounted, and his flight was in truth a commercial voyage rather than an adventure of hardship.

Still taking the view of the air traveler, engine and airplane endurance was demonstrated in a sensational manner by the flight of Forest O'Brien and Dale Jackson in the *St. Louis Echo*, which remained aloft over St. Louis and vicinity in July for 420 hours, 21 minutes and 30 seconds, and was ordered down, while still able to continue, when it was decided that the objects of the test had been accom-

to stop loading itself that a general public market is being sold, and go after the new markets outside of the industry itself. But, of course, to continue exploiting and serving the market that existed.

Just what market is the best is a subject that is at present cause for much speculation and argument. There are those who believe that small plane sales to the public at large will be the future backbone of the aeronautic industry. In other words, similar to the pleasure car in the automotive industry. On the other hand, there are those, too, who declare that aviation is a non-recreational transportation industry and that the small plane, or plane as plane, will only be to the industry at large what the motor bus is to the shipping industry.

We take no sides in such a controversy at this time,

phased. The practicability of refueling in the air had first been demonstrated by the Army at the very onset of 1929 when the "Queen Mary" with its three engines and crew of five, under the command of Major Carl Spatz, remained in the air for 150 hours, 41

Re-fueled the pilot. From under this machine's clipped structure, mechanical fuel-line took off, flew short, and landed in place entirely by instruments.

minutes and 15 seconds, exceeding even the duration record for higher-than-air craft.

Another notable factor in the year's developments was the Daniel Guggenheim Fund for the Promotion of Aeronautics, which was discontinued at the end of 1929 with the announcement that its work had been completed. Under the auspices of the Fund, Lieutenant

James H. Doolittle, Army pilot, culminated a series of blind flying experiments by landing a plane entirely by instruments while seated in an enclosed blind cockpit, thus scoring a definite victory in aviation's war against one of its most persistent enemies—fog. The Fund also funded, in the Curtiss Tanager, the winner of its Solo Aircraft Competition. When the rules of that contest, for prizes aggregating \$250,000, were announced in 1927, several designers and manufacturers freely declared that the plane called for would be safe because it never would leave the ground.

Since the air traveler is quite paradoxically interested in getting back to his starting point, no reviewer can overlook the significance of the flight from New York to Los Angeles and return in 36 hours, 49 minutes and 48 seconds of actual flying time, made by Captain Fred Goetz, who earlier in the year had clipped the West-East transcontinental record held by Art Goebel.

This performance increases in importance when the comparative rarity of two-way record flights and the usual conditions favoring West-East flights are considered. The idea of returning in the air was applied to a two-way non-stop flight by Nick Mazur and Art Walker, who flew the "Spokane Sun-God" from Spokane to New York and return.

In 1929, only three non-stop trans-Atlantic flights were made, indicating that the possibility of successful flights across a watery surface, hampered by treacherous weather is winning in favor of actual experimenting over terra-firma. Of these three flights, the most noteworthy was the 4,200 mile non-stop journey of Captains Ignacio Briones and Francisco Iglesias over the South Atlantic from Senlis, Spain, to Ithaca, Brazil, in a plane bearing the impressive name of "Jesus del Gran Poder" (Jesus the All Powerful). The original destination of this, the sixth crossing of the South Atlantic,

The opening of the 1929 National Air Races at Cleveland

AVIATION February 11, 1930

AVIATION February 11, 1930

Unloading the first Douglas in Lockheed

had been Rio de Janeiro, but exhausted fuel forced the flyers down.

Two crossings of the North Atlantic were registered, both from the United States to Europe. These, made by Ives Zischel, Ross LaBrosse and Armand Loeb, Jr., in the "Yellow Bird," and Roger Q. Wilcox and Lewis A. Yonkey in the "Patriot," added little to what had been learned from previous trans-Atlantic flights, although both planes landed in Spain, a country not hitherto visited by a man flying directly from the United States. The "Patriot" continued to Italy, another nation which until then had not been reached with an aerial good will ambassador from this country.

GERMANY, with government subsidies being steadily reduced, contributed to transport development by completing the Dornier DO-N flying boat, which successfully made a 100 mile flight with 369 passengers on board. A German, Lieutenant Drer, of Koenigsberg, set a new endurance record for gliders by remaining aloft for 14 hours and 44 minutes and one of his fellow countrymen, Willy Naumbach, broke the world's altitude record for airplanes.

Naumbach's record of 41,295 feet was only 2,655 feet greater than that of Lieutenant Apollo Soehnle, U. S. N., who ascended to 39,140 feet in a land plane, and later, on the same ship, equipped with balloons, set a new seaplane altitude record of 38,555 feet which is as yet unbroken.

New standards in speed, as well as altitude, were established in 1929. Squadron Leader A. H. Orlikov, of the British Schneider Cup team, attained an official average speed of 337.7 miles per hour in a special trial after the Schneider exp. race, which was won by Flying Officer Henry R. D. Waghorn with a speed of 328.64 miles per hour. To date, Squadron Leader Orlikov has gone faster, faster than any other human being.

Of importance to the progress of aviation, although scarcely of interest to the present-day newspaper, was the successful flight of Rear Admiral (then Com-

mander) Richard E. Byrd and his companions over the South Pole, which, coupled with the Commander's North Pole flight of 1926, completed the conquest of both poles by airplane.

Among the non-spectacular but highly constructive accomplishments of the year was a flight of almost 700 miles, from Detroit to Langley Field, Va., in an airplane powered with a Diesel engine. During the flight, which lasted 6 hours and 50 minutes, the engine burned only \$1.68 worth of coarse fuel. It has been

Jack H. Davis (in the cockpit) and Capt. Roy Collins members of the 1929 Air Ship, under Donald Eastwood's control, arrive in Lockheed Air Engine

estimated that a similar flight with a gasoline engine of like power would have cost approximately \$24 for fuel alone.

The national Air Races of 1929 held at Cleveland, O., were an index to the growth of aeronautics in general and of civil aviation in particular during the year. More successful than any such races in the past, they set a new attendance record, attracted unprecedented public attention throughout the country, and introduced a number of features new to this annual event, perhaps the most outstanding being the part played by civil aircraft in entertaining the crowds. The Wars and other aerobatic teams shared nearest with the military and naval aviation groups, the latter including Colonel Lindbergh, flying as guest leader of the "Navy High Five," and the Tusculum "Mystery Nine," a non-military product, thrilled spectators by its maneuvers and speed. The "Mystery Builder" confirmed earlier expressions of its fitness by winning the free-for-all race, open to any type of craft, with a speed of 194

miles per hour, defeating the fastest military ships on the field.

The 1929 races also marked the debut of women in the national class. A women's race country derby from Santa Monica to Cleveland, the first of its kind ever held, was among the nine long distance derbies which provided the opening of the races on August 24th, and women's events were listed among the 35 closed sports races on the program.

These races also presented a wide variety of novelties which proved interesting to those engaged in the aeronautical industry as well as to the public. An airplane was successfully "packed up" and launched again by the U. S. Navy Douglas biplane, and a passenger plane was transformed from a dirigible to an airplane for the first time in history. The *Cervus Autogyro* flown by its inventor, demonstrated its frequent flights its ability to land without rolling forward. Charles [Spivey] Kelman performed loops and other acrobatics, including long upside down flights, in a tri-motor Ford. The Navy's new advanced dirigible made its appearance.

The national air races and their accompanying National Aeronautical Exposition, which came to its end on September 2, were followed by the Fifth National Air Tour, which starting from Detroit on October 5 and covering 5,607 miles, proved to be the most complete wide area exposition of civil aircraft ever held. Planes of every size and type were represented, from tiny open cockpit sport ships to huge cabin transports. Two open cockpit planes, both Waco's, finished in first and second place, and the largest of the transports, a tri-motored

Wichita, Kansas, home port of several of the entries.

Among the important annual events of the year which produced a world's record was the *Camel Trophy* race at Anacostia, D. C. which was won by Lieutenant W. G. Tomlinson, U. S. N., with a speed of 162.82 miles per hour. Lieutenant Tomlinson was easily over the other twelve planes in the contest and established a new speed record for standard military machines.

Preceding the trans-Atlantic flights of 1929 was another international flight in another direction, that of George W. Haldeman, who flew non-stop from Canada to Cuba in 12 hours and 36 minutes. It was the first non-stop flight between Canada and the West of the Americas, although not the first non-stop flight across the northern and southern boundaries of the United States.

MORE THAN A SCORE of records of various kinds, including marks for speed and altitude with pay loads and for planes in certain limited classes, were made in 1929. Some were broken, and some show indications of standing for some time to come. Shortly after the "Question Mark" had shown what standing to be an aerial acrobatic, for example, a number of accidents were made upon the Army's record and several starting but short land marks were set up. Robbins and Kelly increased the duration record from 150 hours to 172 hours, Newcomb and Mitchell brought it to 175 hours, and they were still finally routing from the start when Maclell and Reiterman, the "rough brothers" of Fort Worth, stayed up for 246 hours and 44 minutes. This was in July, and before the month ended, O'Brien and Jackson were aloft on the flight which settled the before-mentioned question for what seems to be an appreciable length of time. They lived in their airplane for more than 17 days, and traveled a distance estimated to more than equal a circuit of the world at the equator.

In the field of women's records, competition likewise was keen. During the past the number of licensed women pilots were more than doubled, and women finally were from the National Aeronautical Association in United States representative of the Federation Aeronautique Internationale, representative of a women's classification for record purposes. Miss Evelyn (Bobbe) Trout, Miss Louise McPhee, Miss Thaddeus, member of the National Women's Air Derby, and Miss Elmer Smith, in the order named, established solo endurance records for their sex, only to be beaten by Miss Maryse Beane, of France, whose power record is 36 hours and 46 minutes. The first Miss Thaddeus record was credited with the present women's altitude record, her mark of 23,956 feet exceeding previous figures set up by Miss Thaddeus and before Miss Thaddeus, Lady Heath. Miss Amelia Earhart established a women's speed record at 184 miles per hour.

One of the last records to fall, toward the close of last year was the long distance race, as though 1929 sought to celebrate before passing into oblivion, the 26th anniversary of man's first sustained power driven flight. Captain Donaldson Cates and Paul Goebel, flying over a measured triangular course at Larois, France, covered 4,984.8 miles, in 33½ hours, setting the distance record made when by Clarence Chamberlin on his flight to Germany. Compare their distance with the 130 feet covered by Orville Wright steadily 25 slots years before!

For 11 days they did it. O'Brien and Jackson taking on supplies.

Ford and the Curtin Corder, finished third and fourth. Twenty nine competing planes and ten accompanying ships started in the race, and 24 of the competitors finished. All an accompanying plane and one plane which was withdrawn from the contest but joined the accompanying fleet, completed the tour. In several outcrops which prevented planes and pilots from continuing, no one was hurt. Three women started in the race, and two finished.

The first itinerary included twenty states and two Canadian provinces and from the Canadian border extended as far South as Jacksonville, Fla. tracing a number of East Coast cities. The western border

Aircraft Finance

DURING 1929

A Review of Conditions and Developments of Last Year Which Indicates that the Aircraft Industry Today Is in a Relatively Strong Financial Position

By K. REED CAMPBELL
Standard Statistix Co., Inc.

CURRENTLY there is a distinct air of pessimism around in aeronautical circles. A lowered attitude seems to have spread through all ranks of the industry. What is it all about anyway?

It might be well to start off by pointing out adverse economic conditions chalked up last year. According to the computations of the Aeronautical Chamber of Commerce, airplanes and engines produced in the United States in 1929 had a value of \$59,000,000. Ninety-six major aircraft manufacturers produced 6,934 planes which, without engines, had a total value of \$44,450,000. Expressed in dollar value, the commercial output for the period showed a gain of no less than 96 per cent over 1928 results. In the engine division, equally impressive forward strides are evidenced. Engine output for 1929 aggregated 7,378 units, of which 5,517 were for the commercial market. The commercial market product had a worth of \$17,895,500 and the military \$8,600,530. Commercial outputs were 100 per cent above 1928, and military outputs 32 per cent ahead of the preceding comparable period.

Any other industry on the face of the earth that could point back to an impressive record as that world assuredly be proud of the achievement, and justly so.

Getting down to brass tacks, the fact of the matter is that the unusual growth of aviation, in the past year especially, is merely what amounts to an present predicament, unavoidable as it seems. One need only review the situation, however, to prove the case.

The pace set by the industry, but as it has been, does not come compare with the expansion in the ranks of the trade, so that current production facilities are far in excess of requirements. Although great strides in airplanes and engines for the year 1929 totaled \$88,000,000, the evaluation put on the shows of these manufacturing companies at their peak was in excess of

\$1,000,000,000. Total gross receipts were less than one per cent to the market values of these shares, and the net so infinitesimal that positively stable losses are shown as the majority of books.

Following Lindbergh's flight everyone desired to share in the profits indicated from the new, fast and efficient mode of transport. Time, the essence of business, had been conquered to a degree heretofore of a few years ago. There was nothing wrong with this psychology, indeed it can be prophesied that the future pilot will prove its worthiness, but it was useless to expect that companies could be put together faster than airplanes and that all should prosper.

The year of 1928 saw the commencement of wholesale formation of new aviation companies. Some of these concerns were sound, some mediocre, many unneeded and quite a few were inspired more with the idea of selling stock, certificates than furthering the growth of an important development. Inexpensive of personalities, nevertheless, share values that spread as the public scrambled to buy any certificate that had the magic word aviation or any synonym thereof resembled as its fate.

Through 1929, the movement continued. Likewise did a host of other business in growing ebullience. By December, 1929, the Government reported more than 300 individuals, groups or corporations in the United States claiming to manufacture aircraft. "Obviously no error, when it is considered that approximately 30 airplane manufacturers are able to supply the nation's demand for more than six to four million passenger cars per year," observed the report. The same sort of statistic applied to the engine manufacturing division, in fact in every branch of the industry.

The point therefore, that now requires contemplating

Air Transport

DEVELOPMENT IN

A Review of Last Year's Phenomenal Growth and a

IN DEVELOPING regularly scheduled passenger transportation by air during 1929 America has created something which did not exist before in this country or any other. While air travel has been commonplace in many parts of the world, the development of an air transport industry based upon private capital investment without government participation or subsidy is peculiar to the United States. In no other country has the development of scheduled air travel been so dependent upon the enterprise of private citizens, and so divorced from matters of government policy, military or otherwise.

The history of air transport development in this country provides the background for the history of all commercial aviation. In 1927 there was no passenger transport broadly speaking, aerial services being almost entirely confined to the air mail and "aerial service" and ferrying. In 1928 the foundations of an enlarged air transport structure were being laid. The past 1929 has witnessed the development of a network of air routes linking together the major cities' airports with regularly scheduled passenger services. It is evident that during the boom period and subsequent slump in the aeronautical industry, air transport has steadily progressed as the framework around which a permanent aeronautical industry may be created. Transport laws provide a steady

workshop for legislation, upon which commercial factory operations may be produced. Transport flying operations develop a permanent air traffic of constantly increasing proportions. The individuals who go to make up this transport traffic represent the reservoir of air-minded persons to whom can be sold the planes, aeronautical products, or other services which the industry offers to the public.

RECOGNIZING the relation between air transport development and the general growth of the aeronautical industry, aircraft and aircraft engine manufacturers, aeronautical executives, and large investors have provided what amounts to a private subsidy of air transport, tremendous amounts of money having been poured into this development during 1929. It is estimated that \$3,000,000 was expended on developing the facilities of Transcontinental Air Transport alone before the first public flight was made. The difference between this private subsidizing and the subsidies provided European operators by their respective governments lies in the fact that the governments do not expect to receive back any of their money, whereas the American private investors are counting upon future profits to break back the original outlay plus a substantial cash profit.

The phenomenal growth of America's air transport

1929

Forecast of Future Progress

By CHARLES F. McREYNOLDS
People Unit Editor of Aviation

operation during 1929 proves the American policy to be correct, at least for American conditions. Not only have air routes been extended to all important points, and passenger traffic totals boosted, but the most innovative attack upon every problem connected with air travel has brought such great progress during the one year of 1929 that air transport gives every evidence of being headed for a profitable future. Adequate terminals have now been provided generally throughout the country, various routes have taken steps to synchronize their schedules to better advantage, both with each other and also with existing water, rail, and bus lines, the number of schedules per day is rapidly increasing, use of equipment in use has in some cases tripled, night flying is already becoming popular, and programs are being made in the solution of dozens of technical problems such as fog flying, radio communication, radio beacon development, and radio direction finding.

Whereas in 1928 the United States operated but 16,667 air miles as compared to 38,340 for Germany, the leading European country, the figure was increased to 35,000 miles of Airways for this country before the close of 1929 while no European country extended its air routes aggressively. In passengers carried the United States has jumped from 93,713 in 1928 to approximately 85,000 for 1929, but still trails Germany, whose 1929 total was approximately 115,000, about the same figure as for 1928. In passenger miles, however, the United States unquestionably leads the world, since our most heavily travelled routes are considerably longer than those of Europe.

IN AIR MAIL the United States continued to lead with a total tonnage for the year of approximately 8,000,000 as compared with less than 2,000,000 lb. carried by France. The fact that the United States, hopelessly outclassed by Europe in 1928, is now regularly operating more miles of air routes, and flying more passenger miles than any other two countries of the world put together, is probably the best index of the strides this country has made.

The fact that established survey miles approximately doubled during 1929 is chiefly attributable to the inauguration of new passenger routes rather than to old routes, as a national air mail network was well estab-

lished by the close of 1928. Some 40 new routes were leased by the Department of Commerce during 1929, of which 34 were passenger lines exclusively. This condition is probably best illustrated by the developments which occurred on the Pacific Coast during 1929. The mail routes there at the start of the year were not added to during the entire year, the only changes being that Boeing and Western Air Express rearranged the bi-weekly schedule over the established transcontinental mail route. Passenger route rates were increased from approximately 4,600 ms. at the end of 1928 to 9,000 ms. at the end of 1929, and rates flown over passenger routes increased from \$200 to 25,000 per day. Over one route, Los Angeles to San Francisco, the number of daily schedules was increased from two each way daily to ten each way daily. So miles of passenger routes approximately doubled, rates flown daily tripled, and at least one schedule was increased to five times the original number of daily arrivals and departures. Although progress has been exceptionally rapid on the Pacific Coast, somewhat the same general rate of development holds true for the country generally.

ANDER CHRONOCORP of transport development for the year brings out a number of interesting high lights. On January 2, 9 and 11 respectively the Pan American routes from Miami to Nassau, Miami to San Juan, and Cleveland, Great Zane to Miami, were inaugurated carrying mail three times weekly. This was our first great step toward comprehensive air service between North and South America, and those services will eventually, as it is presumed, be the basis for a great system of intercontinental commercial airways. On Jan. 23 Southern Air Transport started the Houston to New Orleans mail route.

On February 4, Standard Air Lines, of Los Angeles, extended its tri-weekly Los Angeles-Tucson service to El Paso, Texas on a daily schedule and by affixing a working agreement with the Texas and Pacific Railway inaugurated one of the first, if not the very first air-rail services. Another outstanding development of the month was the formation of the Pacific Coast Aerial Express. Operating a pickup and delivery service in conjunction with night air bus, it represented one of the first efforts to develop a comprehensive aerial express system.

During March the Southern Air Transport lines opened daily passenger service between Brownsville and San Antonio, Galveston and Dallas. Texas Air Transport (later Southern Air Transport) started daily passenger service between El Paso and Dallas, and Pan-American Airways opened the first direct air mail route to Mexico City, operating daily from Brownsville, Texas. Also during March a San Diego-Los Angeles passenger service was started by Pictowski Airways, a subsidiary of the Pictowski Bus Co., representing the first entry of major bus-line interests into airway operations. Other important developments of the month were the assigning of 33 radio frequency bands to air transport operators, and the installation of ground-to-plane radio communications by Boeing and National Air Transport.

During April the Southwest Air Fast Express (S.A.F.E.) was organized and began operations between Dallas and Kansas City, also Tulsa-St. Louis. Colonial installed a double daily passenger schedule on the New York-Boston route; and other routes were placed in operation by Southern Air Transport, Thompson Aeronautical Corp., flying passengers across Lake Erie with amphibians, and United and Marine.

May saw the inception of a double daily schedule on the trans-continental mail route, flying mail from coast-to-coast with the loss of but one business day; regular night passenger flying between San Francisco and Salt Lake City by Boeing; the proposal of overseas Zeppelin mail and passenger routes by the Goodyear-Zeppelin interests; inauguration of the Santiago (Chile)-Cruzeiro (Coral Zone) route by Pan-American Airways, providing the first direct air mail link between the two Americas; and the inauguration of other routes by Western Air Express, Nevada Air Lines, Universal Air Lines, Pitcairn, Colonial, National Parks, Pictowski and Thompson.

In June both Universal Air Lines and Western Air Express provided trans-continental air-rail passenger back-ups. The Western Air Express route between Los Angeles and Kansas City, 1300 mi., representing the longest daylight passenger route in this country. Other air-rail arrangements were effected in the mid-west by S.A.F.E. and Southern Air Transport lines, several lines began a weekend excursion fare route to build up traffic. Varco Grant started an aerial bus service with 11 schedules each way daily across Puget Sound from Seattle to Bremerton, and a co-weekly passenger service was placed in operation by Delta Air Service between Dallas and Birmingham, constituting the last link in a through air line service following the far northern route from coast to coast. Coastal Airways started several new places for passenger flying over the California Sea and San River, while the Aerco Company used Service flying boats for an all-water service between Boston and New York, the first flying boat service operated primarily for passengers during this new era of air transport.

July was terminated by the opening of the long-awaited

48 hr. Transcontinental Air Transport service from New York to Los Angeles through the cooperation of the Pennsylvania and Arkansas, Togoia and Santa Fe railroads. Further excursion rates were introduced, the Goodyear-Zeppelin weather reporting system on the Los Angeles-San Francisco route was taken over by the Department of Commerce, and various lines were started by N.A.T., U.S. Airways, and others.

During August there were further passenger rate reductions to stimulate volume traffic, and aerial express was inaugurated by Western Air Express, Curtiss Flying Services, and Colonial Airways in cooperation with Western Union messenger service. Pictowski Airways opened direct passenger, mail and express service between Los Angeles and Mexico City.

Routes started during September included a Seattle (Washington)-Miami passenger air service using Douglas Lockheed, and later routes by White-Turner carrying mail, and Midcontinent Air Express carrying passengers. A ground-to-plane mail-pickup device was successfully tested, an international service was started in Havana, and a Western Air Express-Universal Air Lines arrangement housed the coast to coast air-rail schedule to less than 40 hr.

NIGHT FLYING, pioneered by the Boeing Company in May 1 with regular flights between San Francisco and Salt Lake City, was inaugurated by Universal Air Lines, Midland Air Lines, and Western Air Express.

Aerial picture of a Colonial Air Transport biplane "Pictowski"

during October. On most of the routes where night flying was done with passengers, take-offs were made before dark, the plane coasting on to a landing some time after darkness. This innovation proved popular and was well patronized leading to extensive plans for early night schedules on all leading passenger routes. Further rate reductions were made by S.A.F.E. and other lines during October. A model of the Armstrong quadracone was tested, and plans announced for a New York-Bermuda mail and passenger service, using 40-passenger Sikorsky amphibians in conjunction with one Armstrong quadracone anchored midway of the route.

During November Pan-American Airways made provision for passenger flying over the Caribbean Sea air-gate routes, a Los Angeles company was formed to handle air express only and Kansas City-Denver passenger service was started by Mid-Continent Air Express.

December saw the operation of additional aerial ferry services at Chicago and San Francisco, providing water

A Consolidated Commodore biplane operated by Pan American Airways

to land field connections via amphibious planes; further testing of ground-to-plane mail pickup devices, and the withdrawal reduction of fares to approximately 60¢ per mile by Western Air Express, T.A.T.-Midland, S.A.F.E., and other routes. In three weeks after reducing fares, W.A.E. traffic on the S.F.L.A. route jumped one thousand per cent from 45 to 450 passengers per week. Since the first of the year this policy of reduction of rates has opened until it seems probable that passenger rates throughout the country will drop to approximately the same level as rail fares. Complete consolidation of Midland and Transcontinental Air Transport was announced.

At the present time almost every large city of the United States is served by a network of regularly scheduled passenger air lines. The northwest and far north sections of the country are the only portions now lacking adequate direct air transport service.

ALL of this airway development has depended directly upon the Department of Commerce Aeronautics Branch for assistance in development, testing, and lighting of routes, and in many other ways. Among the ways in which the Department of Commerce is constantly aiding air transport are: the establishing and enforcing of air traffic rules; investigating and issuing reports on accidents, matters, and crashes; assembling general data on all phases of air transport, establishing and maintaining civil airways, certifying airways with navigation aids, providing weather reporting service; charting airways and publishing and distributing charts and maps of landing fields; research to improve and increase air transport; publication of air commerce factbooks at regular intervals; resuscitating the development of air ports and zoning of airports; publishing airport data. It is usually apparent that without this cooperation from the Department of Commerce the great strides taken by air transport during 1929 would not have been possible. Without the continued help of the Dept. air commerce would be hopelessly crippled.

Considerable changes were made during 1929 in the average characteristics of flying equipment. The tendency has been toward increasingly higher speeds and

much greater carrying capacities. At the beginning of the year most of the transport planes in service had a maximum capacity of ten passengers. At the close of the year there were 15, 18 and 20-passenger planes in regular service and the new Pictowski P-32, 40 passenger plane was scheduled for regular transport work early in the year 1930, with other designs to carry approximately 40 passengers each now under development by Sikorsky and others. Among the outstanding transport planes developed in this country during 1929 were the Fokker P-32, Consolidated "Commodore" 20 passenger amphibious, Boeing and Keystone "Petroleum" 18-passenger planes and the Curtiss "Condor" for 20 passengers. There were six rapid changes away from existing types, most changes being of a dual nature.

Successful night flying with passengers, first by Boeing, and later by others, indicates the early establishment of night schedules over most of our present routes, thus effecting tremendous time savings for business men. The night plane "Skinner" is still an untried experiment and it may take some little time to educate the flying public to sleeping in the air.

RAILS progress was recorded during 1929 in the development of short-circuit ground (surface) radio communication in the Bureau of Aeronautics, T.A.T., Boeing, and others; the radio-radio altimeter showed promise in tests; much progress was made in developing radio compass installations and in providing radio marking of airways. Based upon the progress of the past year 1930 will be sure to show much greater dependence upon the radio for fog and night flying, and it seems probable that all transport terminals of the future will have radio-compass flying.

In line with other advances was the progress recorded in providing ample ground facilities for transport planes. There is an increasingly evident tendency to separate transport and general flying, and it seems probable that all transport terminals of the future will have installations for flying.

Although complete figures are not yet available on all accidents of 1929 the record for the first six months for transport flying was one death for approximately 1,000,000 miles flown. Probably the figures covering the whole year will be a bit worse, as there was one calamitous accident and several minor ones during the last

A Transcontinental Air Transport plane of Mid-Continent, Midland, Mo.

six months, but as a general thing the public is gaining confidence in air travel.

Rates have been a source of constant worry and excitement. The final lowering of rates to the level of rail fare has been an open admission of the now recognized fact that there are just enough people, even in America, willing to pay the high prices originally charged for the economy of time due to travel by air. Now that the rates are down it will prove most difficult ever to increase them, largely due to the fact that during last summer rate reductions were announced as "summer excursion rates" and consequently the public will look for more such, even though the rates be low the year round. Since we must have volume of travel before we can even find out what possibilities there are in air transport, it is almost inevitable that air rates will continue at a low level, with every effort made to reduce the cost of operation in order to show a profit. Probably no line showed a profit during 1938 as straight passenger carrying, but some were able to pare their losses considerably.

The air transport industry developed rapidly from a large group of miscellaneous air lines at the start of 1929 to a comparatively small number of consolidated systems by the close of the year. Railroads are taking an active interest in developing air travel, as are bus and steamship lines. Also, as the airline represents the most substantial market for airplanes, the factories have begun to bring about consolidation so that we enter 1939 with such strong groups as United, with Boeing, P.A.T., and Stout airlines; Aviation Corp. of America with Universal, Colonial, Southern Air Transport, and Interstate Air Lines, while the General Motors-Packard-Western Air Express group represents a third type of business association, more loosely assembled than a merger. There are two brief final results to be expected from this

industry, the first being to be an air transport directly to other activities of the aeronautical industry so that they will rise or fall as one body. The second and more important is the prospect of a universal travel service providing worldwide air, rail, water, and bus connections through the steadily increasing number of consolidations and working agreements. This latter phase of air transport came rapidly to the front in the latter part of 1939 with arrangements by Middle Air Lines, Western Air Express, Universal Air Lines, Pan-American Airways, and others, to provide rail, water, and air schedules to include various consolidation forms of the country.

During 1939 the public accepted passenger air transport in rapidly increasing numbers and there can now be no question as to whether or not there is need for such a service. Technical work now under way both in connection with aviation and other fields of scientific development promises such rapid improvement in all types of equipment as should make air transport both popular and profitable. Night sleepers keeping in constant communication with operations bases by two-way radio-phones, as well as holding a course by radio aid, are just at the vanguard. Increasing contact is to be expected in planes, and the effort of the designers for improved efficiency and economy is continued. When effort lighter than air equipment will have an air travel cannot yet be predicted, but the performance of lighter-than-air craft during 1939, and the projects now under way in this country, lead great interest to the consideration of airships in connection with new sort of air transport system.

There are outstanding failures to be enabled up against 1939 air transport development in the lack of consideration so far given to developing aerial express. Other countries far outstrip us in this activity and since no other transport system has ever earned profits consistently on the carrying of passengers only, it seems urgent that we should develop express and freight services as rapidly as possible. The possibilities for profit, if such a traffic can be penetrated are most alluring. Many companies are now planning to enter, or have already entered the aerial express field. Mr. Robert E. McCreary, president of Railways Express Agency, has said that what is needed is an express plane capable of carrying loads of 20,000 lb. Of course many potential express shipowners are already being sent by air mail, and the driving force between the proper fields of the two types of service is somewhat indistinct.

During 1939 the transport companies have experimented with every factor bearing on their operations. Equipment, personnel, organization, fares, schedules, advertising, and routes have all been the subject of experiment. We enter 1939 with this period of experiment behind. It is now known that there is a definite need and that people will fly in appreciable numbers, but it has been demonstrated that we need low fares, better travel connections and better synchronization with other transport systems, more frequent schedules, the closest attention to comfort and convenience and coordinated advertising of safety records in order to break down the now recognized reluctance which many persons feel towards the idea of leaving the ground. Upon these things, along with technical progress, the transport lines will concentrate during 1939, with the result that an increasing acceptance of air transport, backed up by phenomenal strides made during 1939, can be expected to raise an ever increasing percentage of American travel and commerce into the air.

LAST YEAR'S

Airport Construction

PROJECTS

By CHARLES H. GALE

Assistant Editor of AVIATION

WHILE most other departments of aeronautical activity were having their ups and downs in 1939, the important work of constructing airports continued to forge steadily ahead in all sections of the country. There were individual cases of retrenchment here and there as modifications appeared wise in the light of changing conditions but, for the most part, the work of building new airports and landing fields or improving established installations made extremely gratifying progress. When the year closed the country was richer by close to \$50,000,000 worth of new airport construction and approximately 100 new municipal and commercial airports in operation which brought the total of the two classes in operation, including federal fields, to about 948. Including the federal fields there are 1,554 plans in this country today.

It is quite difficult if not actually impossible, to secure an accurate accounting of the various items of construction and the amount of money actually spent on them during the year. The announcements of various projects are couched in

eluded. Derivation of a satisfactory index is handicapped further by the fact that many projects have been reported to the magazine without enough detail to corroborate the statistics.

THE figures, therefore, must be interpreted as preliminary and representative only. They may be corrected to indicate a somewhat broader view with the actual cost and volume of construction somewhat in excess of the amounts quoted. Because there were cases of hazy information reported without any expenditures thereon indicated, or of acquisitions of airport sites without their reports of improvements or of general development right through from the purchase of land to the inauguration of the plant, etc., it is impossible to make accurate cross-checks or similar comparisons. Certain figures are included because of AVIATION's editorial policy of including Canadian work wherever possible.

According to this compilation between \$45,000,000 and \$50,000,000 was spent in this country and Canada on

The rich house and hangar at Vancouver's Big Bay, Northview, dedicated in January.

A Western Air Express building near Los Angeles, Calif.

airport construction work in 1929. This money was distributed as general as follows: About 55 new development projects, which included purchase of land, installation of buildings, lighting, etc.; but a complete airport; about 300 hangars; about 30-35 administration buildings; about 10 airport sites, representing acquisition of the land only; about 30 cases of surfacing only, which included runways, etc.; and about twenty instances of miscellaneous installations such as lighting, road building only, etc. Altogether there were an excess of 300

An oblique view of the Alton Municipal Airport with biplane dock.

individual projects ranging from the general airport development to single items of larger construction, surfacing, improvement, etc. The majority of these, or about 175, were municipal projects and about 130 were private, that is, generated by corporations or individuals.

Keeping in mind that these figures are merely representative, we shall analyze the distribution of this work by geographical division. We shall consider East as comprising Maine, New Hampshire, Vermont, Rhode Island, Massachusetts, Connecticut, New York, Pennsylvania, New Jersey, Maryland, Delaware and the District of Columbia. The South will comprise Tennessee, Florida, Louisiana, Texas, Virginia, West Virginia, North and South Carolina, Georgia, Alabama, Kentucky and Arkansas. Central will comprise Ohio, Illinois, Indiana, Nebraska, Kansas, Missouri and Iowa. The North Central will include North and South Dakota, Minnesota, Wisconsin, Minnesota and Canada, while the West will include all the other states.

Surprising as it may be according to this compilation

The new \$1,000,000 group of commercial and office buildings at Roosevelt Field, Garden City, N. Y., erected by Roosevelt Field, Inc.

AVIATION February 15, 1930

the East led in the amount of money spent in airport projects. Our best estimate for this figure is between \$4,000,000 and \$17,000,000. There were between 35 and 60 individual projects, about 25 of which were municipal and about 35 were private. Twenty-three of these would be considered general development projects, under the definition given above. Narrowing this down to specialized improvements not involved in a general development program, we find that there were between sixteen and twenty hangars completed, a half dozen or so administrative buildings, a few cases of surfacing improvements only, and eleven cases where acquisition of airport sites was reported without any further reports on developments. There were between fifteen and twenty airports dedicated in the East during the year.

IN THE SOUTH we find that about \$3,000,000 was spent on various projects. There was about the same amount of activity there as in the East, with approximately 60 individual projects of all sorts reported. The majority of the projects in the South were municipal, there being about 40 or 50 of these with about 25 or 30 falling into the classification of private. There were about twenty general development projects, between fifteen and twenty hangars constructed, close to ten or a dozen administrative buildings, and sixteen cases of airport sites purchased without further report of their development. There were five or six cases of concentration on surfacing improvements, and about twenty airport dedications.

Going into the Central zone, we come across the great amount of activity of all the sections of the country. There were about 90 individual projects, with the majority undertaken by municipalities. It was a small majority, however, since only about 50 municipalities were involved as compared with 45 private concerns. The money spent totaled about \$10,000,000, and this was centered in about twenty general development projects which included the acquisition of land, installation of lighting, drainage systems, hangars, and other equipment to make the complete report. Between 30 and 35 hangars were built, about ten administrative buildings erected and about fifteen cases of acquisition of airport sites without further report of developments thereon. There were about

AVIATION February 15, 1930

an oblique view and one of the hangar at Tulsa; both were completed last year.

fifteen cases of specialization on surfacing problems, and there were between 30 and 35 dedications.

In the North Central area, which includes Canada, we find less to report. About \$2,000,000 was spent in this area, with the exceptional projects far outnumbering the private. According to the report, there were fifteen or twenty municipal projects, and five or ten private projects. There were three cases of general development, eight or ten cases of hangar construction, three or four administrative buildings were erected, and about half a dozen sites acquired without further report of their development. There were about five or six instances of specialization on surfacing improvements, and about ten dedications.

In the West, we find much activity, with the municipal projects again outnumbering the private. There were between 50 and 60 municipal and about 35 private projects. A total of \$7,000,000 or \$10,000,000 was spent in this zone, or between twenty and 25 general development projects with hangar construction programs number about 30, administrative buildings about a dozen or fifteen, airport sites acquired about fifteen. There were five or six instances of specialization on airport surfacing, and about 21 or 25 airports dedicated.

The data for the preceding and preceding airports rather look a strong during the year and the Central Wright Airplane Corp. was about the only one making much progress in this direction, with the exception of companies which have developed their own fields at distant points. Among the latter are the American Corp., Western Air Express, Transcontinental Air Transport-Madison, etc.

ASSESSING the status of the sites being developed, we enter the need toward larger areas. A number of the new projects approach 1,000 acres in size. Much of the work done during the year was to increase the size of airports already established, so that the various fields of obstruction, crisscross landing and take-off areas, etc., might be eliminated. The doctrine prevailed several years ago at the onset of the present airport construction movement, to the effect that in general airports could not be too large, since it was going overboard. This is not so, it should be remembered, to any lack of performance on the part of the planes themselves but rather to the volume of machines operating at given points. Safety and operating efficiency should increase directly with this increase in available area though the number of aircraft increase.

There was a definite trend throughout the year toward permanent types of construction in buildings. Steel, brick and concrete types of construction seem to be pre-

dominant in flavor, and the wood type of construction continues to serve the needs of many facilities. This tendency toward permanence includes expensive concrete aprons, adequate heating systems, comfortable offices, well equipped shops, hard-surfaced runways, and similar installations. There are a further indication that the airport is becoming a firmly established institution.

The buildings which formerly characterized the average airport is fast disappearing under the trend toward considerable attention to architectural details. The advent of architects in the field of airport planning has contributed to this tendency, so that the expensive and costly plans which are being created at the present time are being built more and more with an eye to a greater pleasing architectural design. Even landscaping is included in many of the improvement programs.

THE ADMINISTRATION BUILDINGS made its appearance at many airports during the year. This naturally follows recognition of the need for proper housing of executive and clerical staffs charged with the administration of the airport activities. In some instances these administration buildings have included hotel or club accommodations, in addition to the facilities for the executive himself.

Like work as a basis, the development of an airport never may be considered as actually done. The improvements and incorporation of refinements in the existing plant will just about go on forever. The pace of this development work will be faster in the next few years than it probably will be fifteen or twenty years from now when the period of initial installation has passed its close. This year will see a vast amount of additional or supplementary work in airport officials seek to keep their planes up to date and in step with the constantly changing conditions caused by other departments of aviation.

Most money this year will be spent, not on the continued refinements or improvements mentioned above, however, but on the completion of new construction started last year and the inauguration of entirely new projects. Many expensive and ambitious projects are included in this category, the Aeromarine Branch reporting that it has listed about 1,400 new projects to be undertaken this year as compared with about 900 a year ago. Many of these projects represent only good intentions but they are at least potential with the possibility of actual work as they always represent. It is reasonable to estimate that between \$50,000,000 and \$75,000,000 may be spent this year on these airports and the completion of plans already under development.

The idea of uniform architectural design advances for

the entire airport plant will continue to grow headway this year. The trend in this direction is both interesting and important. Judging from the progress made in this direction in 1929 and the attractive designs characterizing many of the projects which have been announced for this year, it may be prophesied that a distinct period in airport architecture is at hand. Along with this goes the improvement in design, arrangement, location and construction methods and materials, a movement which we will under way last year. Meanwhile the expansion in airport management, including field operations and finance will continue.

THE GROWTH of the airport was amply materialized in 1929 by the holding of a number of conferences on airport problems. Such efforts served to focus the representative thought of experienced men from various sections of the country on common problems and afforded the newer men in the field to increase their knowledge of the subject. The sharing of experience and opinions through contacts and rubbing of shoulders undoubtedly resulted in much more intelligent approach to the individual airport projects, with consequent saving of money and provision for more satisfactory equipment.

The lead in this movement was taken by the Aeronautical Chapter of Commerce through its Airport Section. This Section was responsible for the national airport conference at Cleveland in May and regional airport conferences at Boston, Burlington, Atlanta and Los Angeles during the Fall. Cities are contemplated as an expansion of the program. The Aeronautics Branch of the Department of Commerce co-operates closely with the Section and its representatives offered papers based on information accumulated by the government in various studies of the national airport situation.

Airport discussions were held, also, by groups of professional men not specializing on airport construction. Such groups as the Aynth Association and the Amer-

ican Roadbuilders' Association were included in this category. The latter made a nonexclusive contribution by arranging a national conference on airports at Washington in October under the auspices of its City Official's Committee. Thus, of course, was far the purpose of considering the opportunity in airport construction facing the road builders who have been concentrating on similar problems of drainage and surfacing for many years.

In fact, one of the notable trends of this year was for professionals whose activities include problems akin to those involved in airport construction—such as drainage, runway installation and the like—to make available their years of experience and knowledge to the newer institutions of the airport. Because of the many ramifications of the subject, almost every one of the established lines of general construction and engineering can find something to do in aviation. Apparently this fact is gaining recognition, in the certain boom of the country's airport system.

The Airport Section of the Aeronautics Branch rendered much assistance to the industry through its program of expert advice on various projects and the accumulation and dissemination of helpful information. Following carefully planned itineraries representatives of the Section visited many communities seeking guidance in their airport plans. Individual trips were made from time to time, also, to important points along it. The work will be continued throughout this year.

Valuable contributions were made last year through competitions encouraging new and improved general designs of airports. These competitions emphasized particularly the wisdom of paying a great deal of attention to any airport project to the likely demands of the future. Visiting general passenger traffic of large proportions, these competitions sought to prepare preliminary for improvement in public facilities and means of safety in the ground equipment. The Lehigh Airports Competition which closed in November and the English contest earlier in the year were promoters of such competitions.

1929 Design TRENDS

A Review of Airplane and Engine Design Tendencies

By LESLIE E. NEVILLE

Technical Editor of AVIATION

of craft increased progressively in double that figure in the last quarter. Several factors are responsible for this, one of these being the increase in the proportion of closed airplanes which seem to be inherently monoplanes. Another is the increasing popularity of the low wing type of monoplane.

REFERRING for a moment to the first of these, it is interesting to note that the proportion of approved designs of closed monoplanes has increased rapidly during the last quarter of 1929 while that of the familiar open biplane has decreased as shown by the curves in Fig. 1. These changes have not seriously affected the totals, however, and the open biplane designs still lead, as indicated in the chart appended to Fig. 1. The open monoplanes have increased considerably during the last half year while the closed biplanes, which showed great promise during the first half, seem to have given way in the last quarter. This is probably due in a large extent to the previously mentioned increased proportion of low wing monoplanes designs that have been approved. There are however two noteworthy transport biplanes, the Curtiss Condor and the Boeing model 80-A, in actual service and this type evades a strong bid because of its lower unit wing loading.

The deplorable lack of sea planes or flying boats is clearly shown in Fig. 2, but it is not probable that this will continue, judging from the number of designers which has been recruited to meet the demand for this type of craft and for amphibians which also appear to have been neglected in the past but probably will not be in the future. Our available information does not, of course, show the proportion of land planes having floatation gear interchangeable with the landing wheels and, as is generally known, floats may be purchased as additional equipment for a great number of the existing types of land airplanes.

Referring again to Table 1, it is noteworthy that

Airport at Wilkes-Barre, Pa. (Air) - Looking NW direction that shows work in progress.

Fig. 1

Fig. 2

the proportion of two engine airplanes approved has decreased while that of three engine designs has increased slightly during the year, and also that a four engine plane, the Fokker F-33, has been approved.

THE LEFT HAND PORTION of Table II has been devoted chiefly to a breakdown of airplane design approvals on the basis of seating capacity, which is a measure of their classification by weight. Considering the proportion of single seat airplanes for the year, which has been plotted graphically in Fig. 3, we find a continuous decrease throughout the last three quarters of the year and no approvals in this class during the last quarter. In fact, the total for the year is but 5 percent of all of the airplanes approved. These figures are somewhat out of proportion for airplanes of this type and

led to its discontinuation. The four and five seat types have increased threefold during the year and now constitute 14 per cent of the total approvals for 1930.

The proportion of six and seven seat machines and, more particularly the eight and ten seat types, seems to have suffered, while the proportion of aircraft accommodating more than ten passengers has doubled. This is undoubtedly due to the movement toward larger transport planes which has been in evidence during 1929.

In the left hand columns of Table II are shown some interesting items which strongly emphasize the unusual increase during the year. The first of these columns is devoted to average values of the useful load—gross weight rate, the general average for the year being .37. In the second of these columns are given average values for power loading which decrease slightly

it is the writer's belief that there is a definite demand for such craft.

The rapid study of the two seat type, particularly at the expense of the conventional three place planes, is obviously due to the demand for airplanes designed specifically for sport and training. Another equally important influence in this case has been the virtual disappearance of the CO-3 engine remaining available following the close of the war and the tremendous demand for a low priced airplane for this engine. This gradual decrease in proportion of three place planes may be attributed also to an even more significant cause—the increasing unity of purpose in airplane design. During the early stages of the industry the three place open cockpit airplane served well as the backbone of production and the "all purpose machine," but as demand became more definitely defined the evolution of this highly serviceable type together with other determining factors have

Approximate chart showing proportion of total approvals for 1930 classified by seating capacity. Below the bar chart are approximate values of wing loading, power loading and useful load gross weight rate in chart.

Table II—Airplane design tendencies by average (continued in Table III). First—Chined—winging. Total proportion of types for the year.

throughout the year, the general average being 157. The third column is devoted to wing loading averages and it is interesting to note that the year's average of 108 is the same as that of the first quarter, while that of the last quarter is 114.

In addition to the analysis of approved types several outstanding factors are worthy of mention. Taking first the airplanes as a group, we have the almost universal adoption of metal as a material for fuselage structures, while wood is still employed in the majority of wings in the small and medium weight planes. An innovation in the form of spars members cut and delivered to the manufacturers specifications has been introduced by the Percy Manufacturing Co. In the heavier classes wood is employed in most cases throughout the structure. The tubular section in stiff used extensively in the low and medium weight classes of steel fuselage construction while open section members are employed extensively where the light aluminum alloys are used in airplane

structure. This is of course a generally used in one case fuselage tubes are used in the wing and fuselage structure of a large commercial airplane. As regards covering material, fabric still predominates, particularly in the case of wings. These were being made in the case of one airplane to use balsa for fuselage covering and plywood also has been used as before in isolated cases. Metal covered fuselages and wings are still being incorporated in designs while a slight tendency toward the monocoque fuselage and promise of a wing of metal composite type has been observed. More specification materials and progress in material control is noticeable and realization of the possibilities of metal skin application has been reached by airplane manufacturers.

Although perhaps not belonging exclusively to 1929, the wing structure of the Boeing SIB-3 is particularly

worthy of mention because of its originality. This together with a monoplane wing developed in Great Britain indicate that perhaps the conventional two spar arrangement may be modified some time in the future. Strength is also felt to this belief by the extreme slowness by some engineers in the question of wings having three or more spars.

From an aerodynamic standpoint the keynote of the year has been clearance of design gained by reduction of parasite resistance as a number of different ways; a reduction of the relatively large proportion of the drag contributed by landing gear as well as outboard engine mountings, and a definite tendency toward better streamlining. This is indicated by the large number of low wing monoplanes of the so-called "delta" type, one of which attained a speed of more than 200 m.p.h. per hour with a 300 hp. engine. A study of aerodynamic interference of various kinds of the airplane structure has begun. Some time has been spent in the study of the

sharp corners have been seen in increasing numbers and the commercial development of the XACA type radial engine cowling has begun. The adaptation of the British Townsend ring, an annular surface placed around

in some degree from the cylinder heads, also is noticeable to some extent in this country.

The relative value of variable lift devices and of various means to produce lateral control at critical angles of attack has been reviewed in the Guggenheim safety manual magazine which has appeared in several articles in AVIATION, while considerable success has been achieved in the use of flapping wing tip airfoils and the mechanism for their control in the Curtiss Tanager which was described completely in the previous issue of AVIATION. Although not as readily apparent as some of the other trends of the Guggenheim magazine, the improvement in methods of setting airplane performance should certainly not be forgotten. The year has marked the introduction of the Avrocar in America and a number of successful test flights of this type of craft.

THE ATTEMPT to build larger aircraft for commercial use and the adaptation of military to commercial designs has been one of the outstanding tendencies of the year, notable examples being the Fokker F-33, the Curtiss Condor and the Consolidated Commodore. While we are concerned primarily with developments in America, a review of the year would be incomplete without mention of the successful flights of the Dornier Do-X flying boat with 169 passengers and of the Fokker G-3, the world's largest land plane. A considerable number of aircraft have also taken place mention of the British dirigibles R-100 and R-101.

Progress has been made in various specialty manufacturing and cooperation of the specialty manufacturers has been very close. Availability of ball bearings for pulleys and control hinges has resulted in a great improvement in control system reliability and greater ease of control of airplanes. Introduction of the Hien-

airline air wheel already has made an impression and its further use may have a profound effect on landing gear design while tail wheels made possible by brake development are also being used in increasing numbers.

More attractive cabin interiors and a tendency to follow automotive practice in this respect is noticeable and greater comfort has been provided for passengers in transport planes. The use of indirectly lighted inter-

Fig. 1

west boards, borrowed also from the automotive industry, is noticeable. New and improved instruments have been developed and electronic is playing an ever increasing part in equipping the instrument equipment of the transport plane. Radio developments include the General Electric radio echo altimeter, which is rapidly securing the production stage, and the twelve channel radio beacon developed by the Bureau of Standards. In the light-tight or field the successful test flights of the EMC-8 metal-clad airship is a definite accomplishment.

There seems to be more difficulty to determine by the engine type followed in the case of the airplane because of the relatively few engine approvals. However, some interesting results have been obtained, as shown in Tables III and IV. In the first column of Table III an average value for the output of engines approved during 1937 is presented, this value being 209 hp at 1920 r.p.m. In the adjacent column the proportion of air and water cooled engines is shown, these values having been presented in chart form in Fig. 6. Referring to Table III, it will be evident that there were no water cooled engines approved during the last half of 1937.

and during the first half 25 per cent of the approvals were granted to engines of this type. Referring to the Department of Commerce list of approved type certificates for engines it is obvious that those in the water cooled class are chiefly in a horsepower range above 500, while the bulk of the lower powered engines are air cooled types. Judging from these figures it seems probable that the upper limit for air cooled engines is at present between 500 and 600 hp.

The question of horsepower range also enters into the problem of cylinder arrangement although this is not shown clearly in the table. It seems, however, that

the tendency is for engines between 100 and 600 hp to be of the radial type, while those below this range are in-line and those above are Vee type. No approvals of Vee type engines were made during the last half of 1937 and the total proportion for the year is much below the proportion for the first half. The radial appears to be on the increase as is also the inverted in-line type, while the vertical in-line remains constant, as shown by the values for the year in Fig. 7. In the classification on the basis of horsepower range the most significant changes seem to be found in the 100 to 150 hp and 200 to 300 hp class. The first of these classes has increased from 16 to 27 per cent, giving a general average for the year of 22 per cent while the second has decreased from 16 to 9 per cent, providing an average of 13 per cent for the year. In the 400 to 600 hp class there has been some decrease and a state of inactivity is noted in the range above 600 hp and below 50 hp. Not a single engine in the 300 to 400 hp class has been approved by the Department of Commerce at any time. The proportion of engine approvals on the basis of power output is shown in Fig. 8.

As to the number of cylinders, shown in Fig. 9 and Table IV, it seems that the seven cylinder still leads with the nine a very close second, that of course being due to the predominance of radial types. Third in point of numbers is the four cylinder and this is due to the popularity of this type in both in-line and vertical forms for relatively light planes.

Fig. 8

case of the airplane formerly using that power plant.

Two outstanding engine developments of the year are probably the successful out-of-the-line flight from Detroit to Langley Field, Va., of a Stinson monoplane powered by the Packard-Cummins engine and the research conducted by the Army Air Corps in the use of glycerine glycol (Prestone) as a substitute for water in high non-pressure liquid cooling. The reduction in radiator area as well as other advantages accruing from this research has already found commercial application in the form of several planes produced by the Curtiss Company and there is still more research work to be done. An increasing use of magnesium alloy is also noticed in aircraft construction and the ground and supercharged types of engine seem to have obtained a definite foothold in America. Progress has also been made in the methods of production of aluminum alloy as well as steel forgings for aircraft engines.

Turbine engine installations necessitating power propellers seems to be attracting the interest of engineers and the use of indirectly long drive shafts to transmit power from engine to propeller has also been made in at least two cases, that of the Bellanca "Tandem" and Junkers G-38.

1930 Airplane Design

Leading Engineers and Plane Builders Venture Their Opinions of the 1930 Trend in Airplane Design

As a corollary to our inquiry on the general trend in the aircraft industry (see page 295) we have also sought the collective opinions of leading airplane designers and chief engineers of prominent manufacturing companies upon the probable course of technical evolution. As in the general questionnaire, we have addressed to those asked to contribute certain specific questions, to wit:

1. What is the general trend of design likely to be, and in what plane (aerodynamic, structural or elements of detail) is greatest progress likely to be made?
2. How much further evolution is to be expected in the near future in the design of very large planes? Do you expect to see projects initiated by responsible and experienced companies during the next year for machines larger than any so far built?
3. How much increase in thrust likely to be in the use of aerodynamic surfaces and striking departures from accepted forms, such as the slatted wing?
4. Which way will the weight of fuselage swing in the controversy between cantilever and externally braced wing trusses?
5. What will be the trend of tail wing loading during the next year of design? Will it continue to rise as for a number of years past, or has a check been reached?
6. Are aspect ratios likely to increase, decrease, or remain approximately constant on the average?
7. Is further progress of metal construction at the expense of wood to be looked for in the immediate future? If so, how rapid is the displacement of

wooden wing spars and other structural members likely to be?

8. Will metal construction continue to be predominant of aluminum or do you anticipate a growing interest in structures of alloy steel strip?

9. What developments are to be looked for in the near future in landing gear design? Do you anticipate the use of larger shock-absorber travel and generally altered landing gears? Do you look forward to the use of wider or narrower tracks? Any striking modifications likely to be made in the landing gear of light planes to reduce the probability of "nose over"?

As in the previous case, also, some of our correspondents have made specific and separate answers to the several questions, and have met numbers corresponding to those employed in the letters and last paragraph.

There are considerable differences of opinion upon most of the topics suggested for discussion. On the whole, however, it seems to be believed by most of those taking an interest in the matter that no very radical innovations are to be expected in design, that the cantilever monoplane will continue to gain in favor, that wing wing loading will remain where it is or decrease somewhat, and that for commercial and industrial reasons, as both, further interest in giant airplanes is unlikely for the immediate

future. There is, of course, a substantial minority opinion as to how fast this majority view. Upon aspect ratio it is hardly possible to arrive at a consensus, except that there is no definite indication of an anticipated general decrease from present practice in collar construction. It is generally agreed by any means unanimously, agreed that metal construction will continue to progress at the expense of wood, and a surprising number

of contrarians speak favorably of steel construction and of the desirability of further study of that material. Concerning the development of landing gear, the general tendency is to anticipate somewhat larger shock-absorber travel and "softer" gear, but without any general increase in load. Paradoxical interest is displayed in the probable effect of the introduction of the air-wheel, so-called.

Bigger Flying Boats—Research on Aerodynamic Noddies—Farequated Wing Loadings—Durand's Triumph

By LEBERT C. MILBURN

Second Vice President and Chief Engineer, Glenn C. Martin Co.

THE GENERAL TREND (wood) now general during the coming year is indicated by the current interest in flying boats, amphibians, gliders and autogiros.

The increasing needs of the North-South American lines, and the Great Lakes and coast-to-coast projects combined with the U. S. Navy's renewed interest in the flying boat problem, will keep about the most rapid and much needed development of American marine aircraft. In this field, as with the airplane, we have been the first to recognize and the last to develop.

The searunner shortly built, now, in connection, has prepared an excellent field for the privately owned and "bat" type amphibians, which can have speed greater than the automobile and the ease of sail at the cruising water level. Its escape from traffic and the ready access to city centers (and all the large close water frontages) which it provides, will be more and more appreciated.

The future for art and sport in flying is always present to grant the more inherent struggle for speed and range capacity. This year is promising renewed interest in the glider and very low power plane. The progress of the last few years in aerodynamics and construction will be expected to unite to produce gliders and soaring planes of unexpected qualities.

This year probably will see also further practical development of the autogiro, possibly to the extent of finding useful applications for this time-for-urgent member of the aerial family.

The reduction of parasite area and the increase of operating versatility, are to be more and more expressed in dollars quantitatively, as the chemist would say, instead of qualitatively, as heretofore. The direct comparison resulting from this definite yardstick will provide new incentive to produce planes which perform and continue to perform with low maintenance.

There is no definite limit to size, and some further effort may be expected for use as such. General progress to size will only be made as required for economic operation and greater pay-load, or greater distance. One would expect to produce planes which perform and continue to perform with low maintenance.

There is no definite limit to size, and some further effort may be expected for use as such. General progress to size will only be made as required for economic operation and greater pay-load, or greater distance. General progress to size will only be made as required for economic operation and greater pay-load, or greater distance. One would expect to produce planes which perform and continue to perform with low maintenance.

low engine barriers, and plenty of room, one expects larger aircraft soon probably.

This year will see further action to find the proper ratio of wing to fuselage, variable pitch propellers, variable camber and other aerodynamic devices which have been presented to the industry in years past.

In addition to the current wing loadings of 8-12 lb. per sq. ft. for landplanes and 12-18 lb. per sq. ft. for larger flying boats, this year may see indications of a return to former unit loadings of 6-8 lb. for private transportation and sport use.

Aspect ratio affecting an avenue of greatest improvement, can be expected continuously to increase, as regards to structural efficiency per unit.

The conversion from wood to metal will be completed as rapidly as quality production grows. Aluminum alloys have definite structural and manufacturing advantages over steel and wood, and will continue to be used generally for planes up to 30,000 lb. gross weight.

The greatest improvement which I expect to see 1930 bring forth is in instruments and navigation. The recent Pacific coast disaster indicates how much handicapped air transport is without further development of means for safe operation in bad weather.

Evolution Along Standard Lines—Restricted Landing Speeds

By REX B. BEISEL

Chief Engineer and Chief Designer, Sperry Aircraft Co.

THE GREATEST PROGRESS in design will be in perfection of detail both structural and aerodynamic. By that I mean a greater attention will be paid to simplicity, light weight and maintenance and in the case of aerodynamic detail to interference resistance and general cleanliness of design. The goal as I see it is to approach the perfect airplane by refinement of conventional design rather than to hope for improved performance through a radical design departure.

In my opinion there is no sound reason for responsible or experienced engineers designing machines larger than those already built. In other words, production of such types would not in my opinion be justified by probable sales.

I am not in favor of aerodynamic novelties or striking departures from accepted forms and do not believe there will be any radical increase in their use. With proper and intelligent design it is possible to build a conventional

the surface considerably better than a great majority of the existing types. This procedure will be conducive to airplane safety, much more so than such design.

I believe there is a tendency to rely on the qualitative type of wing especially on airplanes where top speed is the essential requirement. However, the type of wing structure whether based on rational monoplanes or biplanes, should be governed to a great extent by the type of and requirements of the particular airplane to be designed.

I believe a check has been reached in test wing load through the new Department of Commerce regulation limiting landing speeds to 60 mph. I am in favor of limiting the landing speed and also in favor of keeping landing speeds down to somewhere near this figure both from the standpoint of safety and the effect on the performance of the airplane.

Aspect ratio will increase, i.e., the aspect loading will decrease.

The departure from wood to metal wing construction will and should be very gradual. Metal will not replace wood in the lower price class types until very large production is warranted which will not be in the next few years.

Metal wing construction is more applicable and relatively cheaper on the large than on the small airplane and the fact that the percentage price differential between wood and metal wings on the large multi-engine airplane is small is a factor in metal wing construction. The real advantage of metal over wood construction is in my mind not apparent except under the influence of certain climatic conditions. As far as long life is concerned, there is little advantage of metal over wood material as there is little to be gained by designing an airplane to last ten years when it will be close obsolescent or be off or partially crashed after a month or shorter period.

If I believe metal construction, in the industry at least, will continue to be predominantly of aluminum, because of the experience and familiarity already attained with its use in fabrication in the airplane industry of material, cost of construction, and the tendency in American manufacture to get away from "progressive" design, which is more or less general with alloy steel strip construction.

If I see no reason for any marked change in landing gear construction. With greater use of the Clevis and brakes, the improvement in landing gear functioning has been as marked as but to require any great additional development. More and better landing fields also greatly influence the shore. The use of "side" tracks seems to have been generally adopted along with the added use of landings. Here again the width of track, unless the landing gear is attached directly to the fuselage, is a function of the design of the airplane as a whole, i.e., the forward fuselage or the externally braced monoplane usually takes a wide gear with apparently no disadvantage in using same. I see no reason for strikingly modifying the landing gear of small planes to reduce the landing gear tendency. The effort to obtain good performance with low power requires a clean gear and I believe with proper design the tendency to move over can be reduced to a minimum.

I am very much in favor of the liquid-cooled engine in the larger horsepower, i.e., 500 hp. or over. Whether Piston-cooled or not, I expect to see the liquid-cooled engine used more and more extensively. The use of ground propellers and a super-charger on the liquid-cooled engine will offset any advantage of the large

air-cooled engine. With the necessity of using the N.A.C.A. or a similar code on the air-cooled engine to obtain performance comparable with the liquid-cooled engine, the additional weight and complexity of installation, especially from the standpoint of engine and oil cooling, makes the air-cooled engine installation from the airplane designer's viewpoint much less attractive.

Cantilever Wings and Lower Aspect Ratios—Giant Planes Improbable

By H. C. RICHARDSON

Director of Engineering, Allied Engine Industries, Inc.

THE GENERAL TENDENCY of design appears to be toward multi-engine cable planes with high or low wings. The principal effort will be to clean up aerodynamically, avoid all possible protrusions by either streamlining or retracting the landing gear. Cantilever wings of the monoplane type will gain an popularity.

Very large planes have been proposed and now even under construction. Perhaps this has arisen as anticipation of future public interest, but appears premature and ambitious and hardly warranted by present production methods. The proposed planes appear reasonable and should be popular. Twenty- to thirty-place planes of commercial success. Fifty- to one-hundred place reasonably possible of attainment with little chance of commercial success—and over one hundred more or less fantastic and visionary propositions at the time. Even larger planes are realistic but can hardly prove efficient without considerable research and development.

The increased progress of the Guggenheim competition will undoubtedly advance the movement toward inherent stabilizing elements, and may produce some inventions equal or superior to those demonstrated in this contest. I look for greater progress in better proportioned controls and the avoidance of emergency equipment.

The increased performance demanded will undoubtedly lead to greater use of cantilever wings, the first step being the semi-cantilever, perhaps with wing fences.

The demand for performance will tend to stretch design limits to the upper limit permitted by the Department of Commerce regulations and will tend to move design to some degree by the Guggenheim competition results.

The cantilever effort will probably result in a decreased wheel track.

Wood construction will principally remain in popular types and in new experimental designs which, if they obtain popularity, will be quickly translated to metal. However, there will be a price deterrent.

Durandism will probably continue its sway. Too little has yet been accomplished in alloy steel strip construction in this country to expect much advance in that type.

Combination steel and hollow steel and concrete were popular. Twisted wheels in large planes may be accepted. The big stroke oleo is partly dictated by Department of Commerce deep seat requirements. Oleos used still further to study to eliminate peak landing.

Increased use of brakes and tail wheels will tend to force the main wheels forward, and require oleo tail

R. B. BEISEL

H. C. RICHARDSON

H. C. RICHARDSON

shells, or hollow wheels on all wheels. This added weight makes this less of a handicap than with the present construction.

More Viable-Lift Devices—Caniliver Wings—Better Landing Gears

By T. P. WRIGHT

Chief Engineer, Central Airlines & Motor Co.

IN GENERAL, I feel that there will be continued activity on the part of designers towards the aerodynamic improvement of airplanes. I think this is more likely to be achieved than structural improvement.

I believe the number of large planes intended in the near future will be less than in the past similar period, because of the very high expense involved in the development of such projects.

Accompanied by the rather difficult market for these ships, based on the showing as far made by air transportation companies. However, I feel that this is only a temporary lull based on the immediate reaction from the present ships, and that eventually the sphere of usefulness of the airplane will be more in the field of large transports than in other. In all probability, however, in the near future no new very large ships will be developed.

I am quite certain that a very considerable use of the various means at hand for increasing lift by special auxiliary wings, etc., will take place during the next one to two years. It seems, too, based on definite information I have at hand, that this is one of the most fruitful sources of aerodynamic improvement and one which should be refitted to the utmost.

In all probability, during the next year there will continue to be a considerable number of externally-braced monoplane wing airplanes placed on the market and perhaps because of the smaller difficulties in design, there will be a preponderance of this type. However, I feel that there will be more internally-braced wings than heretofore and that there will be a further trend towards this type which will eventually become predominant.

It is my belief that wing loadings will definitely increase, not accompanied by increased stalling speed, but rather due to the aerodynamic innovations introduced by such experiments as slots and flaps, decreased stalling speeds. In other words, I feel that there has been a definite action on increased stalling speeds and that during the next year the trend will be towards slightly slower speeds rather than higher.

I think there will be a trend to smaller aspect ratios as the larger aspect ratios are difficult to obtain with monoplane designs, particularly of the internally-braced type.

I feel that the trend will definitely continue towards all-metal construction, probably bringing to light new types of construction of various interesting forms. I believe wood spars will continue to use on ships of 3,000 lb. gross weight and less for a considerable period of time but that all ships of over 5,000 lb. gross weight, using wood spars, will be constructed hereafter.

I believe that undoubtedly interest in steel strip construction will become apparent within the next year or two although I believe that duralumin will still predominate in actual construction for some time to come.

I believe that the idea landing gear has just come to stay, and that in general the single, or triad, will be increased. This tendency may be developed somewhat by the combined use with the old type of the Goodyear Moonbeam type (or similar type of other construction) tires. It is also my opinion that the tendency will be towards wider tracks and that retractable landing gears will make their appearance quite a number of designs. It is also probable that some light planes will be developed which have definite provision for prohibiting or lessening the utility of raising over, although I do not believe the next year will see much effect in this direction.

Steel Depends on Demand—Wood and Metal Remains in Balance—Trimming Parasite Resistance

By A. A. GASSNER

Chief Engineer, Fokker Aircraft Corp.

IT SEEMS to us that the greatest progress in design during 1930 will be made in improving the aerodynamic characteristics of airplanes. It is not to be expected that revolutionary changes in wing section or fuselage shape will be attempted to obtain better efficiency for the complete airplane, but that the design will be refined to eliminate as far as possible all details which are creating turbulence in the flow of the air without creating a proportionate amount of lift. This can be achieved, for example, by making the leading gear retractable into wing or fuselage, by rounding off sharp corners of the fuselage, by eliminating air reflecting brace struts for wing and tail surfaces, by refining the exposed cooling air-cooled radial engines, for which purpose the NACA cooling and the Townsend ring have shown the way for future developments.

A. A. GASSNER

The design of very large planes seems to be more an economic and financial problem than one of engineering, science or art. At the present time there seems to be no immediate need of airplanes of larger size than already built in this country. The further development of large-sized airplanes, however, is needed for transatlantic service.

The introduction of aerodynamic research into commercial ships for the year 1930 is not very likely. The Curtiss Autogiro and the dotted wing are both about ten years old and have made comparatively little headway. Any new and striking departure from accepted standards has to be developed both streamlining and aerodynamically, which is usually more difficult than the aerodynamic perfecting of accepted standards. Commercial ships can only be sold in quantities when they give low service troubles and every new design has to be put through a process of experimentation before it is fit for production.

The caniliver wing has decided aerodynamic ad-

vantages over the braced wing, and the two dungs appear to be surprisingly similar in weight. The final choice is made in considering production cost, as the tapered, caniliver wing is more expensive to build than a braced wing of uniform rib section. This applies in opposition to the outward wing for ships in a class where low price is the chief consideration.

The unit wing loading for landplane seaplanes to have reached an upper limit with about 38 lb. per sq. ft. An increase of the maximum lift coefficient of the wing by increasing the mean aerodynamic camber would tend to decrease efficiency. As landing speeds have to be kept at 60 m.p.h. for single-engine, and 65 m.p.h. for multi-engine planes, a further increase of wing loading is not to be expected.

The average aspect ratio of the wing will probably remain in now, that is between 6 and 7.5. An improvement in wing characteristics can be obtained, however, by increasing the taper as has been done on the Fokker "F-32," the Rohrbach "Ronne" and Junkers "J-38."

Wood has always been, and still is, a very reliable material for primary and secondary structure of airplanes. Its advantages and disadvantages compared with metal construction balance about evenly and we should not expect rapid changes from today's picture as far as commercial planes are concerned.

I believe that duralumin will be used more extensively than strip steel. British airplane manufacturers probably felt the necessity to develop the metal construction on account of the absence of aluminum deposits in the British Isles. The welded steel tube fuselage construction will probably continue to be used on most landplanes.

Landing gears will be built more generally with oleo-pneumatic or oleo-spring shock absorbers. As airports all over the country have been improved considerably, a shock absorber travel of 8 in. seems to be sufficient for medium-sized planes with not too high wing loading. The moving over of planes equipped with landing gear can be avoided by placing the landing gear far enough forward.

Comfort and Convenience—Ample Reserves of Power

By H. A. ROCKS

Avro Aircraft, Ford Motor Co.

THE GENERAL TENDENCY of airplane design in 1930 will be to fulfill the demands of 1929. For passenger work these demands were for more comfortable and economical transportation with greater speed and safety. As the tendency of air travel has passed to competition with established surface transportation, it is essential that the air passenger have accommodations and comforts equal to the railroad passenger. The 1930 plane must be made more quiet by not only decreasing the sound at the source, but by its absorption within the cabin. Cabin vision, more comfortable and vibration-absorbing chairs, useful interior lighting, service berths, and side and under toilet facilities must be incorporated. Radio receiving sets installed as standard equipment will prove of valuable assistance to the pilot as well as passengers. In some large cabin planes the weight of materials installed specifically for passenger accommodations, and

included in the empty weight of the plane, reaches the astounding figure of 8 per cent of the plane's gross weight. The introduction of refinements will demand a structural revision to yield a lower structural weight, using both sections of higher fiber fabric and materials of higher specific strength/weight ratios.

The demand for higher engine output should be met, not by an increase in power plant size, but by increasing the propulsive efficiency by improved propeller design and more efficient power plant location, also by a reduction in overall plane drag effected by lower resistance engine cowling, landing gear wheel streamlining, more efficient fitting between units such as wing to fuselage, engine cowling to fuselage, and landing wheel-to-landing gear.

More safety will attend passenger transportation as the use of multi-engine planes becomes universal. Certainly the successful passenger planes of 1930 will be of this type, providing they have been designed to yield real performance and control with one or more power units "out."

The added safety in multi-engine operation maintains with the ability of the plane to continue flight with one or more of its power units out of operation. It is necessary, then, that the airplane be controllable and have sufficient control for operation on the runway with at least one of its engines "out" in order to be superior to the single-engine plane. Reference to a topographical map of the United States shows that most of the Mississippi valley with an absolute ceiling with full load of less than 5,000 ft. with one engine "out" should not be feared, while west of the Mississippi a ceiling of 6,000 ft. is necessary. Tri-engine planes with engine units of about 500 hp each are the most economical because this horsepower yields the most satisfactory fractional engine performance.

The trend of passenger transports has been toward larger planes with the result that the gross loads and passenger capacities are steadily increasing. This has been caused by a demand from state operators for greater economies, in the belief that the large plane would reduce operating costs. The 30- to 40-passenger transport provides a cabin of larger size yielding more satisfactory passenger accommodations with a given maximum cabin air speed. A 40-passenger transport plane with a day capacity of from 30 to 40 and sleeping accommodations for 15 to 20 passengers provides our nearest approach to railway competition. A plane of this size, however, is more costly to build and does not lend itself to economy production.

The full caniliver wing construction will continue to gain in favor as cruising speeds increase. It presents an aerodynamic and structural challenges which airlines staff in performance and appearance. By using a thin airfoil section at the tip, tapering both in plan and thickness to a high lift section at the fuselage, a high speed, efficient, and rate of climb is obtained, with a relatively low landing speed. An internally braced wing demands a more careful design study in order to equal the structural weight of the externally braced wing. It is particularly useful to all-metal wings. The use of the thick section necessary for structural strength largely obviates the need for heavy bracing, and the ribs and spars which further increase the mass of the plane.

The unit wing loading during the next year should tend to increase in passenger transports. The unit wing loading of an airplane depends on many other factors than gross weight and wing area. In multi-engine planes

where low power loadings usually are used it is possible to use a higher wing loading. The proper proportion of power to wing loading with a given airfoil is one which can best be determined by experiment. The engine tests, tests, actual use of airfoil data, loading and power type, relation of wing to fuselage, type of bracing, all have a direct bearing on airplane performance and should be considered when discussing unit wing loading.

In multi-engine planes the wing loading will probably reach 18. This is necessary to achieve structural weight, increase the high speed, and place the planes on a more economical basis, as they increase in size. As engine sizes become more highly developed, airports more numerous, and multi-engine planes with highly developed power brakes and softer landing gear in universal use, it will be possible to land passengers at the higher speeds created by increased wing loadings.

Weight values for internally braced monoplane will average approximately constant between 7 and 8, with 7½ as an efficient average. Below this figure the aerodynamic efficiency of the wing falls off rapidly and above 8 the increase in efficiency is obtained with too great a structural weight. The plan form of this type of wing will increase in taper for increased rigidity.

The all-metal airplane is the ultimate in plane construction for all types. The trend will first be toward the larger planes when, because of greater protective dimensions, the advantages of metal construction are more obvious. Metal construction offers many advantages in the aircraft industry. Railway cars, auto bodies, building and bridge structures originally made in wood are now made in metal. Metal is manufactured and treated by exact processes. It is capable of exact analysis, is homogeneous, and its strength can be relied on within a few per cent. It is easy to analyze, and wings made from metal have a definite aerodynamic value independent of temperature and humidity. The life of a properly designed metal plane is at least five years, or 3,000 flying hours. Metal construction calls for exact accurate detail and fabrication, more expensive tooling, but is better suited for quantity production and yields a more refined and substantial product than wood. Metal construction in the small plane will be largely of duralumin but the larger plane offers a possibility of using materials of widely varying specific gravity. In the present duralumin metal plane the central section and wing tips have high margins of safety because it is not practical to use this material less than 0.910 in. thickness owing to the danger of distortion or creating the sections during fabrication and service. Steel for these parts of 0.0035 in. for the same weight is even less satisfactory as it also lacks local stiffness. Obviously the most economical material for these parts would be magnesium alloy, the lightest of commercial metals, which could be used as thin as 0.012 in., properly protected, at a saving in weight of 20 per cent over duralumin. Duralumin finds its use for sections from approximately 0.0040 in. to 0.120 in. in thickness. Where heavier shells are required it is required to be more successful in use steel because of its higher specific weight/strength ratio, especially in compression. The main advantage in the use of steel over duralumin is in the fabrication of the joints, using smaller gage plates, lower rivets, saving in weight as well as fabricating cost.

The comparison of steel and duralumin will not be successfully made because of their difference in expansion and methods of elasticity. However, it will be a structural advantage to have one section of a wing near of duralumin and an adjacent ribbed section of alloy steel. The ideal large plane is one in which the protective extremities of the wings and fuselage and control surfaces are of properly protected magnesium alloy, with the intermediate and major sections of the wing and fuselage of duralumin and the middle portion of the fuselage and wing root of alloy steel. The design of landing gear will vary considerably depending upon the class of plane. The small training and sport plane will undoubtedly make use of low-pressure tires, using three without shock absorbing members. The greater fire supporting area will be of value when operating from small fields where soft surface conditions may exist. The large transport planes operating from airports will use the present type of tire to reduce drag, but will become considerably the shock absorber. As these planes become larger and landing speeds increase, the pressure with which a landing gear can be made decreases. This will necessitate landing gear shock absorber travels as great as 24 in. It is anticipated that wider track landing gear will be more in favor to facilitate landing and taxiing. With suitable spring location and the addition of more powerful brakes the possibility of coming over will be properly designed for to actually allow the plane to bear down on a forward slide in the event of an emergency landing where severe braking conditions are demanded.

Better Economy by Cleanliness of Design— A Chance for Stainless Steel in Airplanes

By C. F. PORTER

Chief Engineer, Eastern Aircraft Corp.

THE PRESENT MAXIMUM apparently is to carry more pounds for less money, and this should lead to improvement in designs of fuselages. The horsepower per pound of payload must be decreased. I expect to see retractable landing gears and power plants installed in the wing.

A capacity of 40 passengers seems to me to be a reasonable economic limit at the present time. The problem is to find the way for our present transport airplanes before experiencing with size outside our engineering experience.

The use of stainless steel such as shown in the Corbin "Dangler" should, possibly, increase the popularity of sport flying. The value of their use on transport airplanes is yet to be demonstrated.

I believe large ships will probably develop into flying wings with the power plants inside the wing, hence the aircraft principle will spread. On small ships I look for a continuation of the present monoplane type.

Wing loading should increase on large ships, with increase of effective power-output brakes. On small ships it will probably stay nearly at present values.

No radical change in aspect ratio would seem to be indicated.

There seems to be an action to replace wood by metal where the former meets structural requirements with less weight and cost. Large ships will naturally have complete metal structures, but I expect to see the wing

C. F. Porter

beams of small ships continue to be made of wood until production quantities justify metal structures.

I look to see increase in use of high-strength alloy metals, especially "Stalium Steel." Its high strength makes its strength weight ratio equal to or better than duralumin and its ability to resist corrosion is superior to steel.

In the case of large airplanes, I look for retractable landing gears with longer travel and very powerful brakes, this to go with increase of landing speed. In the case of light airplanes I expect landing gears to be able to take a parallel landing, especially in the case of airplanes with slots and flaps.

Radicalism May Be Worth While— Cantilever Wings Most Economical

By H. V. THADEN

Gen'l Manager, Pittsburgh-West Airplane Co.

IT SEEMS to me that the greatest improvement is going to have to come in aerodynamics and cleanups of designs. Structurally there will undoubtedly be some improvement, but I believe it will require a prodigious amount of effort to make any worthwhile lowering in structural weight from today's conventional. I am rather confident that metal construction will undoubtedly result in a different improvement from the weight saving that is now being sought, but even so it is hard to remember more than a thin to fifteen per cent decrease in weight.

Speaking as one with no experience in the larger planes, I can only voice the opinion that I believe the larger planes are economically justifiable and I expect to see considerable development in these larger planes.

Although I personally have been rather conservative in departing from conventional aerodynamic characteristics, I am beginning to be of the opinion that it is only by some departure from our present methods that we are going to get any real improvement. The ideas of the slotted wing and the removal of airfoil boundary layer are extremely interesting, but so far I haven't had the courage to act upon in any of my designs.

My views on cantilever or externally braced wing structures are likewise fairly set. It is my opinion, after having passed through all the stages as design from the airplane truss to the semi-cantilever and finally to the full cantilever, that the latter is the most practical. Its relative structural simplicity as well as its higher aerodynamic efficiency are distinct points in its favor. Of course I am assuming a rigid cover of some sort. Practically all my work has been with some form of rigid metal covering which acts as an assumed structural member as well as a covering. Recent results in a monocoque type of wing which we are developing confirm this opinion.

From all my own observations it seems to me that wing loadings are going to continue to rise, but probably at a slower rate. It would seem that with the better fields and the greater number of fields that spread up around 60-70 mph could be justified. I know that I have tested cowbirds faster and faster landings as my

H. V. Thaden

personal flying. Of course, the lower landing speeds would be desirable but the question is how to get them and still keep any kind of decent performance figures.

I should say emphatically yes to your question as to whether metal construction is to show further progress in the immediate future. Some of the most recent results of the Army and others besides ourselves indicate that a practical type of metal-covered wing structure is not far off. Just how long it would take the manufacturers of conventional airplanes to appreciate and change over their systems is something I don't know.

Based as I more or less am because of my experience in a light alloy field, I naturally am wedded to that kind of material. I have found that the impossibility of handling the necessary thin gages of steel in the shop has retarded the use of this material. Even the thinner gages of duralumin which would be more tender as thick as steel of the same strength, have a definite minimum gage from a shop standpoint. Of course all my thoughts along this subject are predicated on an all-metal construction including the cover, and I don't quite see how alloy steel could successfully compete in this type of construction.

I anticipate the use of larger shock absorber travel and generally softer landing gear with wider tracks on any of the conventional bi-planes or high-wing monoplane. I have been advocating the low-wing ship for some time, and in this connection I anticipate the use of cantilever "Stalium" type landing gear on the low wing. Whether the necessity of the average pilot will enable him to use a retractable type of landing gear, I don't know. I rather question, however, whether this type, with its additional costs, will become truly popular on any except the racing planes.

Designers Must Watch the Operators— Larger and Faster Planes— Engine Coolings

By GÉRARD VAILLÉ

Chief Engineer, Lockheed Aircraft Corp.

COMMENTING on the probable trend of aerodynamic engineering during the coming year, it is my opinion that we are in a period in which, generally, the airplane must justify its use upon an economic basis.

Assuming this statement to be correct, it naturally follows that the manufacturer must adjust his product to the current needs of the operator. While, undoubtedly, all efforts should always be made to increase the safety of aircraft in every way possible, the stimulus of the last year have shown that with present competition the safety of air travel compares very favorably with other modes of transportation, so that it appears that the problem of solving the public on the safety of aviation is general in more an educational than an engineering one.

At the present time it is perhaps more important that the operators be furnished airplanes which will enable them to carry at a profit such passengers or cargo as will be attracted by their advertising and educational campaigns.

The type of airplane needed, of course, depends upon the operating conditions on each particular line. Several of the larger airlines have recently put into effect drastic

reductions in rates. (In some instances, as great as to make the fare by air lower than the Pullman fare made for the purpose of increasing the volume of passenger traffic through port areas), and thus reducing the cost operating cost per passenger. Assuming the expected volume of traffic is obtained, additional savings in costs may be effected by the use of larger planes, instead of merely raising rate plans of the same size. Thus, it may be predicted that the current year will see a number of new designs in use—perhaps as large as 30-passenger capacity. It is natural to expect that such development work will be carried on slowly by the larger manufacturers.

Considerable progress in the development of very high speed planes of smaller type may be expected during the coming year. The need for such equipment exists with road lines, and with lines which cover over a long route in one day, in order to avoid night flying with passengers. Naturally such through lines would not secure the volume of passengers served by the shorter lines operating between large adjacent cities. Their rates would be higher in proportion as would be also their operating expenses. Plans for such lines will be developed to carry from four perhaps ten passengers, and have cruising speeds in excess of 150 m.p.h. In the case of such long-distance routes, the slight increase in operating cost would be well offset by the time saving element, which is one of the prime incentives for air transportation.

As to the manner in which such lines will be in evidence in the design of such planes, it is only possible for an engineer to give his personal views. The question of cantilever wing structure versus external bracing is one which necessarily must be considered as depending upon the operational requirements for the particular case. It would seem reasonable to assume, however, that the trend should be toward cantilever construction because of the saving in head resistance which can be accomplished through the elimination of external bracing.

As larger planes are reached, it will be necessary to resort to wings which employ deeper sections at the root, and which are tapered more strongly than is customary in current designs. It may even be advantageous to increase the amount of taper to the extent that the lift distribution along the span no longer conforms with the optimum elliptical distribution. Naturally, such procedure should decrease the aerodynamic efficiency of the wing slightly, but it is believed that sufficient structural advantages can be secured so that the saving in weight would more than pay for such a loss.

The use of retractable landing gear in designs which are laid out to accommodate them makes it possible to increase the landing gear's approach. With such an increase in landing angle (pitched), of course, with the use of an air field having a flat topoff lift curve and controls which are effective in the region of stall it will be possible to reduce the roll on landing considerably without the extension use of brakes. And, with the regular roll of the plane being kept the same, the wing area may be reduced and thus the cruising speed of the plane increased without decreasing the safety of the plane.

It is the writer's personal opinion that the development by manufacturers of flexible covering for radial engines has been successful. The advantages to be derived by the use of such covering on planes properly designed to incorporate it, seem sufficiently attractive to justify the expense of additional research and development by the individual manufacturer.

No Radical Changes—Steady Tendency Toward Metal—Steel Looks Promising

By H. LAWTON

Chief Engineer, Travel Air Co.

I DO NOT LOOK FORWARD to any radical change or development in the design and the construction of airplanes during the year of 1959. Gradual refinement in details, structural and aerodynamic forms is contemplated.

It is unlikely that clothed wings will greatly increase in favor this year due to an apparent divergence of opinion as to their merits. The recent success of the ducted wing airplanes entered in the Guggenheim Safe Plane competition may, however, give an impetus towards their further adoption.

Though plans for larger and more powerful airplanes than now exist will probably be made, it does not appear to me that the present demand policies will intensify construction schemes. Possibly it will be the primary, however, of making the demand fit the case rather than the case fit the demand. I cannot predict to be a prophet in this respect.

Undoubtedly the wing bracing will gradually evolve to simpler and fewer external members, in the direction of incorporating the bracing internally within the wing. The unit wing loading will probably increase slightly in its average figure, though at present, it appears to be about as high as is practical. The value of the unit wing loading is a function of number, distribution, size and quality of airports as well as the aerodynamic properties of the airplane. Personally, I favor a reasonable figure for the unit wing loading. The trend of positive regard to wing aspect ratio will probably remain about the same as was used the past year.

It appears logical, and the general design trend is, indicative of a long evolution towards metal structure displacing that of wood. No resolution as design can be anticipated. The remaining blocks seem to be the lack of efficient type design that can be economically fabricated.

The probable trend will be the gradual substitution of metal parts for wood, such as ribs, etc. The next few years will probably see greater development of the direct stress steel structure. Designers of the future would use a preferable stressed covering material owing to its low relative density. The low relative density is important, since the stiffness of the covering varies as the cube of its thickness and for the same weight a greater surface would be of stiffer construction made of denser than if it were made of steel.

There is a growing tendency to provide landing gear with shock absorbers of the oleo-type and with larger energy absorbing capacities. This is necessitated by the increased wing loadings and resulting higher landing speeds.

Inasmuch as it is the purpose of the shock absorber to shock shock, whomever it carries absolutely, the capacity the more satisfactory it would prove in this respect. I expect to see this year some development in the oleo shock absorbers of greater shock absorption capacities.

H. Lawton

Aerodynamic Progress by Mass Production—Higher Landing Speeds

By KENNETH M. HOSAN

Chief Engineer, Stearns Aircraft Co.

I BELIEVE THAT an evolutionary change in aerodynamic or structural details will be made this year. I feel that the structural and aerodynamic qualities of the airplane are a considerable and very closely related thing, and that we will be able to improve the aerodynamic cleanliness by building airplanes in such quantities that we can change the structure to suit aerodynamic refinement more than we do at present. I believe that the greatest progress is going to be made in structural refinement in that parts and assemblies which are now generally hand-made will be almost entirely machine-made. This, of course, is a question of more production. We are now at a stage to gain knowledge where we could go ahead with structural changes to that a great deal of the body of the airplane and wings could be made from stampings. I feel that the number of steps being sold is justifying the only remaining factor in this development of a lower priced and improved airplane.

With regard to the design of larger planes, my ideas are mainly passive. I do feel that considerably larger planes will be built and that, since structural design is the determining factor, we cannot go much further without increasing the size of wings over our present types of structure, because of the relatively large increase of dead weight with the increase of size. One solution appears to be the use of a higher landing speed and I feel that this, to a limited extent, is allowable and a reasonably safe practice in the case of the new increases.

With regard to the question of aerodynamic activities, I feel that such applications to slotted wings, flapping surfaces, etc., will only be used in ships designed to meet special conditions. In my opinion, for ships designed for the general public, the smaller the number of such complications the better. We cannot go much further in landing speed, I feel, that it can be secured more passively by an increase of wing area, and if we must maintain or increase the top speed on the design it can be done more cheaply by the use of power. I believe our speed will be increased more by the use of considerably lower power loadings than by the use of track airplanes.

Regarding the question of cantilever or externally braced wings, I think the question will be solved from the standpoint of cost. If the production is such that the wings will be used almost exclusively, the cantilever wing will probably soon so secure that the externally braced wing.

I believe that the wing loading will continue to rise. This, I think, will be determined to a considerable extent by the availability of landing fields. The average pilot could not get a plane down when lands unsuitably better than the present airplane if the field were smooth and sufficiently large.

Regarding aspect ratios, I believe they will remain about as they are at present.

Metal will replace wood for structural parts as soon as production warrants the use of tooling for it. I think that steel will allow several types of production methods, which may replace to a great extent the use of aluminum in the primary structure.

With regard to landing gear, I feel that we will have greater landing gear shock absorber travel and large low-

pressure tires. I believe that wheels will be wider than those in general use at present. Landing gear can be put further ahead of the center of gravity if the power is increased to help lift the tail in getting off. This will prevent more over landings necessitated prevalent on the smaller planes.

I believe that the biggest trend is going to be the use of a great deal more power. Ships will also be designed for more comfort, ease of handling and other items which the general public is beginning to demand.

Refinements in Slots and Flaps—Gradual Increases in Size

By F. S. HUBBARD

Chief Engineer, Bellanca-John Aircraft Co.

THE GENERAL TRENDS of airplane design at the present time and for future development is toward increased efficiency. This means improved aerodynamic shape and cleanliness of design, improved and lighter structural shapes with a trend to lighter metal construction. These phases are even or less dependent on such other in order to obtain more efficient airplanes.

As the development of large planes any increase in size is dependent upon improvement in design and size of the power plants. Large planes should also be multi-motored, especially for passenger carrying, and should maintain flight with only a portion of their motors functioning to ensure safety of operation. I believe as passenger and freight carrying increases the size of the planes will progress steadily and we shall see larger planes in the future, both in landplanes and seaplanes.

The slotted wing, flap and landing stream are rapidly being developed and their success was exemplified in the Curtiss "Tanager" which recently won the Guggenheim prize. Their ability to decrease the landing speed and improve the control at stall has been proven and I believe with a little more refinement they will be adaptable especially to commercial aviation.

In regard to whether cantilever or externally braced wing arrangements will predominate, I believe each has its place. In seaplanes wing with cantilever wing will more and more come to the front as the metal wing is developed. However, for biplanes, which will also be used due to their smaller span and compactness, the externally braced arrangement will predominate.

As to wing loading it may increase slightly with the use of slots and flaps. However, we are beginning to reach our limit in this respect, especially for landplanes where low landing speeds are desirable. Higher wing loadings with higher landing speeds for airplanes are possible, due to their larger landing facilities.

Aspect ratio will not increase appreciably any more than it has in the last few years. This is due to the fact that cantilever wings are restricted to certain aspect ratios. Externally braced biplanes which are normally allowed a greater aspect ratio because unsuitably, require too much external bracing, and take up unnecessary space and weight are increased. Also the gain in efficiency is nullified after a certain aspect ratio is reached and any further gain is offset by structural and other considerations.

Metal construction is rapidly coming to the fore due to the difficulties in obtaining good wood and also the uncertainties of this material. Metal lends itself to pro-

duction and will be looked upon more favorably as production increases. I believe both duralumin and alloy steels have their place in design. With the improvement in alloy steels such as stainless steel and the proper use of heat treating, steel will be used more and more, especially on large structures where forgings and joints can be more readily handled in steel.

Designers of landing gears are attempting at all times to improve this part of the airplane, especially in taking shock loads. This requires better methods for taking these loads and usually a larger shock absorber travel. The trend is dependent to some extent on the span of the airplane, and I do not believe will be materially altered in percentage of travel to span. In the design of landing gears for light planes, it will not take a special type of landing gear, but the arrangement will have to be modified to meet the various requirements. The greatest field for thought in the future in this phase of design will be to improve landing gear for aeroplanes, as this type will become more popular as time goes on.

In conclusion, the airplane of the future in my opinion, is going to be a gradual refinement of the present-day airplane rather than any revolutionary type. This will be brought about by increased efficiency in design, more efficient and reliable power plants, decreased landing speeds due to devices like slots and flaps, increase in controllability of the airplane, especially at low speeds, and increase of efficiency in taking off and getting into smaller fields.

From the Foremost American Authority on European Developments

By JOHN JAY DUE

Technical Assistant in Europe, N.A.C.A.

I HAVE RECEIVED your questionnaire on the probable trend of American technical development in the near future. Before taking up in order the various points you mention, a few general observations may be made.

I believe that great attention will be devoted to designing transport airplanes by those companies competent to create large units. The existing stock of small single-engined cabin aircraft would appear to realize some continued intensive production of this type. The recent drastic cuts in the long-distance air line firms, whether wise or not from the economic standpoint, have at least had the effect of increasing the proportion of actual to potential payload and thus will result in order for large units for replacements and additions to the existing fleets. The flying public is now accustomed to the comparatively room accommodations available in the light planes, and would resent being asked to fly in small machines on long stages. New types of large transport monoplanes will be developed, having three or four engines mounted above the wing and all driving tractor screws.

It is hoped the intensive efforts all made to develop a really satisfactory multi-engined flying boat of about 15 tons total weight, of reasonably clean aerodynamic design and requiring the minimum amount of attention. Notwithstanding their weight, water-tight hulls should be incorporated in the hull, the floor should likewise be water-tight so that a damaged bottom will not sink the ship. The engines should be mounted high enough to prevent damage to the propellers by

water. Advances should be taken of the great experience acquired by the Naval Aircraft Factory at Philadelphia in the art of building flying boats, experience which would not be placed at the disposal of manufacturers seriously undertaking the development of such airplanes.

In answer to the second question, I certainly do not expect to see any larger machine than the Do X built during 1930, either at home or in Europe, although Dr. Dornier has prepared designs for a larger type. The reply to the third point, as to whether there will be an increase in America in the use of aerodynamic sections such as domed wings, would appear to depend upon legal rather than technical considerations. Personally, I have always been a strong believer in the efficacy of the automatic disc in providing control beyond the normal stalling angle. Due to the action of Air Commodore Chausser, former Director of Technical Development, the automatic disc has been made standard on all service aircraft in the Royal Air Force except those of the single-engine parent class. It has likewise been sold to the Swedish Government and is being tested in France, Italy, Poland, etc.

While hesitating to venture a prophecy on the question of cantilever versus braced structures, I believe that the present ratio will remain approximately constant, such manufacturers continuing to use the type of structure characteristic of his production in the past.

The most severe landing will probably continue to rise as for some years past. The wisdom of this trend, so far as land machines are concerned, is very questionable, as it is impossible to be always within a reasonably short distance of a field allowing a high speed landing.

Due to structural rather than aerodynamic considerations, it means probably that aircraft weight will remain constant on the average and will not increase.

It is to be expected that metal construction will continue to make progress and that wooden spars, still used primarily on the ground of economy, will yield to metal when satisfactory sections are developed.

Notwithstanding the excellent results obtained in flap-lift with alloy steel strip, I do not believe that it will be adopted widely in America in account of the comparatively high cost of production and the degree of skill required.

The success of the American adaptations of the British rear landing gear has been most striking and continued development is certain. Such gears combined with air wheels should make land landings almost unimpeachable. Trends should be made as early as compatible with airplane structures.

In closing I may emphasize the vital importance of our engine manufacturers quickly developing reduction gears and superchargers sufficiently rugged to withstand hard service. Such equipment will be essential if reasonable pay loads are to be carried over the mountain passes of North and South America. It would also appear that liquid cooled engines have been too long neglected, and that serious efforts should be made to improve our position in this respect. The recent work of the Army Air Corps at Wright Field in chemical cooling, while undertaken primarily for service use, has interesting possibilities commercially.

Further contributions to this symposium will appear in next month's issue.

THE Engine Builders LOOK AT 1930

*A Symposium of Engine Design Tendencies
by Power Plant Engineers and
Manufacturers*

W. M. Miller, chief engineer, Motor Cars	212

OUR collective forecast of 1930, prepared by the personnel of the industry itself and of the interested government departments and educational institutions, is brought to a closer by providing a synopsis upon power plant trends. The general technology remains pretty much the same as those affecting the general trend in aeronautical development.

In response to the questionnaire the specific inquiries put were:

1. Is the liquid-cooled engine likely to regain substantial favor during the coming year, or do you consider that the general trend towards air-cooling will continue?
2. Do you expect air-cooled engines to continue predominantly radial or do you anticipate a decided trend towards the development of in-line V and X forms?
3. What are the most important improvements in engine performance that you anticipate in the near future? Do you expect substantial further increase in reliability or in life between overhauls? Do you think that substantial reductions in weight per horsepower can be anticipated?
4. Do you expect that it will be possible to make further increases in compression ratio without change of basic fuel?
5. Are you in favor of a marked improvement in

the standard fuel as governed by specifications, increasing on uniformity and its anti-detonant qualities, with the object of permitting increases in compression ratio and brake mean effective pressure and of decreasing weight and frontal area?

6. What is your opinion of the probable early future of the compression-ignition type of engine (whether or not two-cycle Diesel) in aircraft powerplants?

7. Do you look forward to marked innovations in cylinder arrangement, such as the introduction of double-row radial or X engines?

8. What is the prospect for the use of materials outside the ordinary present range of commercial practice, such as magnesium for crankcases and cylinder heads, or of new manufacturing processes, such as the forging of cylinder heads of duralumin?

9. Are you satisfied with the present type of engine mounting and the ways in which it is applied?

10. Are any marked simplifications or improve-

ments in necessary installation such as "fitting" to be located for.

1) Does the present relation between the responsibilities of the airplane engine designers fairly give or do you believe that there should and will be a trend towards the building of unit power plant systems, with the engine designer providing for standard mountings, cowings, and accessory location?

Upon these points there is, of course, a natural difference of opinion, and in few cases, if any, was the majority complete. There is, however, a general agreement that the liquid-cooled engine will make good progress, especially in the largest sizes, but that, on the other hand, the air-cooled radial will continue in the leading position in the field. Few of our contributors viewed a hope for any further substantial reduction in weight per horsepower existing progress shown in reliability and durability and new look forward to any radical advance in comparison rate without improvement in fuel.

The use point upon which unanimity is most nearly achieved is the fifth in the questionnaire. Almost without exception those who replied expressed themselves as strongly favoring better fuel, even at higher cost.

Upon the Diesel engine there is wide variety of

opinion, but with considerable bordering upon sanguine pronouncement. Few of the designers offering comments made any bright future for the use of liquid fuels, although they cylinder heads, but many expressed the strongest hope for magnesium alloy castings, in crankcases and elsewhere. Several entertained the hope of decided improvement in the present method of mounting engines, and quite a majority of those answering indicate opinion that the engine designers should take more responsibility for the mounting and for the general installation and arrangement of the power plant section of the airplane. On the whole, the engine designers, like those concerned with the airplane structure will not confuse in looking for any radical solution.

In closing the introduction and turning the floor over to those who have been good enough to make contributions to this symposium, we cannot refrain from pointing with pride, as we have felt inclined to do in the two previous instances also, to the extraordinarily broad representation of the industry that is presented here. With hardly an exception, the chief engineers of the important American engine manufacturing companies are present and speaking—fully and frankly. To them, as to those who replied to our other questionnaires, of which the results have been set forth on earlier pages of the present issue, very hearty appreciation is due from ourselves and from our readers.

aircraft purposes. I believe air-cooling will continue to be used because of the greater pay-load that can be carried as well as the greater reliability which is inherent in this type of engine.

2) The radial form of air-cooled engine is likely to predominate because it gives the simplest and lightest powerplant. It may be necessary in very large power units to go to another type. Undoubtedly, the weight of other air-cooled types is so much greater that it will then become a question whether it is desirable to use air-cooling or not.

3) The most important improvements in engine performance in the near future should be directed towards reduction of operating costs. To this end greater accessibility will be provided, so that overhauls may be made with the minimum number of man-hours. In the near way periodic inspection will be facilitated by improved design. The greatest problem to be solved is that of structural fatigue. This necessitates the replacement of worn parts—frequently entire—several times during the life of the powerplant. Paid and of course, these are quite reasonable and form only a small part of the operating cost per mile. For this reason, I doubt whether there is as much need for improvement in this direction as in others. Further reduction in weight per horsepower will be very slow. It may can be worth while to increase the weight of commercial powerplants to obtain greater durability.

4) Compression ratios cannot be raised appreciably without the aid of special fuels. As a matter of fact, the tendency has been to use ratios that were too high for the existing fuels.

5) A great gain in engine performance can be made by improved fuels. As a matter of service record it has been proven true and again that it is cheaper to operate

on the very best fuel. Better fuels will make possible higher power output, somewhat less weight per horse power and better fuel consumption depending largely upon the anti-knock quality of the fuel.

6) The future of the Diesel type of aircraft engine is most uncertain at the present time. Compared with the present Otto cycle engine, the Diesel powerplant weight including fuel for a long-distance flight, would apparently be less. It is doubtful whether there would be any saving of the overhead engine were operated as a more suitable fuel. Interestingly the Diesel engine must stand higher stresses and therefore is heavier per horse power. A partial solution of this difficulty is two cycle operation, which seems almost a requirement if the Diesel cycle is to be considered in all for aircraft. For any normal commercial operation in the United States there seems to be little or no improvement to be had from the Diesel. At most it may be a question of fuel cost but pay-laden carried for a given horse power. It seemed at one time as though the Diesel was particularly desirable for Zeppelin work. Now that gas has been introduced, which obviates the need of valving processes being gas, the Diesel cycle seems much less attractive for this purpose. It may be a real solution to the fire hazard and radio interference with the Diesel cycle, but it is doubtful whether it will be used in view of these considerations alone.

7) Almost all the possible kinds of cylinder arrangements have been already tried, so that I do not look for any innovations in the line. Normally, as the ward to any innovations in the line.

8) Aside from fuel developments, the greatest improvement in engine performance will come through the use of new materials. At the present time, further weight saving is not as essential to commercial aviation as reduction of fatigue. The savings in weight under 15 lb./hp. that might be made would have relatively little effect on the operating costs of a commercial company.

9) The present time, the lighter the material, the better its fatigue characteristics seem to be, especially at operating temperatures.

10) The mounting of radial engines is about as simple as can be devised. On the other hand, there may be a trend towards complete retractable power units with at least lubricating system and controls. However, such an arrangement has not been found worth while in the automobile field and I doubt whether the weight involved will make it desirable for aviation.

11) It is doubtful whether there will be any further simplification in accessories of their installation. As a matter of fact, the accessory requirements of commercial aviation are likely to be more and more numerous. As a result, the powerplant is very likely to become more complicated rather than simplified.

12) The satisfactory execution of a relatively complicated set of mechanical units always depends upon cooperation between the designers of the various units and a mutual understanding of each other's problems. Fortunately, the industry has reached a point where the plane designer approaches the problems of the engine manufacturer and both in most cases has solved. This situation has contributed quite considerably to the excellent performance of our commercial aircraft during the past year.

More Air-Cooled Fees—Better Mountings, and More Coherent Installation—Diesels Sometimes, But Not Yet

By P. B. TAYLOR

Army Chief Engineer Wright Aeronautical Corp.

THE LIQUID-COOLED engine is still in the experimental stage, and will in all probability not emerge before the end of this year. Air-cooled engines will continue in popularity for all service with the possible exception of high performance military days. I believe the air-cooled "V" engine possesses most of the advantages of liquid-cooled engines with the added advantage of simple installation with either fixed or retractable cowling.

2) I believe there will be a decided trend toward lighter "V" and "X" forms for large size engines, which will be carried to some extent into the smaller sizes.

3) I believe a substantial reduction in weight per horsepower of aircraft engines will be accomplished in the near future. Increase in reliability and life between overhauls is also essential for the success of aviation. The two developments are opposed to a certain extent but improvements along both lines will be accomplished.

4) It will be possible to slightly increase the compression ratio without changing the basic fuel. This will be accomplished by better cylinder cooling.

5) I am strong in favor of the use and wide distribution of better fuel as governed by specifications. This alone will permit decrease in weight per horsepower and increase in reliability of aircraft engines.

6) I believe the compression ignition engine is probably the type which will eventually replace the present piston, ignition units. This development will come slowly and will not be a radical step in engine development.

7) I look forward to marked innovation in cylinder arrangement, such as the double row radial, the "X" engine and other more radical forms.

8) The use of magnesium is already practical but expensive. I believe the possibility of increasing the horsepower as given by the use of a more satisfactory method of reducing specific weight than the use of special light alloys. If the ultimate is desired from a cylinder, the use of forged aluminum heads is undoubtedly necessary.

This process is also expensive and will probably be confined to military and racing types for the present.

9) I am not at all satisfied with engine mounting structure and its method of application. The engine is at present used to complete the mounting structure. I am of the opinion that the correct method of engine mounting is a three point support on the engine, which will be designed into the engine will be able to take the mounting strains through the crankcase. This type of mount does not permit of a misalignment as three points are completely accurate.

10) I believe the oil tank and oil cooling device may become a part of the engine supplied by the manufacturer. This will result in a simplified design of installation and an increase in reliability. Accessories will continue to be the bane of the engine designer.

11) The engine manufacturer will eventually supply sufficient cooling to cover the engine unit. It may also supply the exhaust manifold and oil tank. His design must be sufficiently universal to be adapted to a large number of aircraft. It is a waste of time to design a structure and prevents the use of universal cowling carried below the

Better Accessibility—Improved Standard Fuels—Skipped on the Diesel

By GEORGE J. MEAD

Head, Aircraft and Turbine Division,
Ford in Military Develops Inc.

IT IS DIFFICULT, whether we can expect any startling improvements in engine design without some very definite investment from the manufacturer and the customer. Without their help there will naturally be a steady improvement of detail resulting in better and better powerplants. On the other hand, measured by weight per horse power or fuel consumption there will be relatively little gain. As far as weight is concerned, it may even be desirable to attempt compressing powerplants in order to reduce the fatigue value of various parts.

4) Liquid-cooled engines of over 200 hp. may prove of value for military purposes. It is believed that air-cooled powerplants give superior military performance in smaller units. The growth of the liquid-cooled development is dependent upon a definite reduction in drag as a result of smaller radiators that are necessary with water-cooling.

To use of the high temperatures, it is no longer possible to water-cool the oil, so that it now becomes a question of whether the qualified water and air-cooled radiators will have appreciably less drag than the single water-cooled radiator inlets required. To obtain the best results with liquid-cooling it is necessary to design for it and the subsequent higher operating temperatures. For com-

George J. Mead

the engine cylinders as a radial engine. An air-cooled "V" is a decided improvement in this respect as the cooling which contributes to engine cooling can be supplied directly by the engine manufacturer without interfering with installation.

Relation Between Engine Form and Fuselage Form—Better Fuels Not to be Counted On

By ROBERT INSLEY

Chief Engineer, General Electric Co.

THE liquid-cooled engine will segment but not supplant the air-cooled type in the next year or two. The development of the high temperature liquid-cooled engine promises problems the solution of which will owe less to money than to ingenuity. Liquid-cooled engines will require installation high speed airplanes and in types of engines such as general engines and the two stroke types in which air cooling is not the best to be desired. That the development of low and Vee type air-cooled engines to avoid the excessive drag of the large radial type will have a considerable influence on the form of the liquid-cooled type. The air-cooled engine receives, has distinct advantages for the purely commercial operator who is not interested in the last possible mile per hour, which will extend its popularity in spite of the high speed characteristics of the liquid-cooled type. The liquid-cooled engine will play an increasingly important part but cannot be expected to do more than high speed specialty acts for several months to come.

2. The increasing success of several inline and Vee type air-cooled engines has demonstrated the practicality of these types. The present excitement about the liquid-cooled engine, whose chief raison d'être is to be desired, promises a definite field of installation for a type of engine which offers reduced drag without the additional weight of the liquid-cooled system. That it must be remembered that the two principal advantages of the inline or Vee type air-cooled engine over the radial type, reduced drag and reduced vibration, vary greatly in importance with the types of installation and size of engine. For instance, what would be the benefits of a line or Vee engine installation on a round-bellied craft like the Lockheed or F4U? On a radial engine installation on a B-29? Will its inherent advantages be offset, justify the existence of a line engine of 100 hp or less in comparison with a high grade radial engine? Can anyone present physical proof that the small radial engine (of up 400 hp or less) is of necessity a rougher engine than the corresponding line engine, or less efficient aerodynamically when installed to the same degree of cooling? The line and Vee air-cooled engines will find increasing participation in the larger sizes.

3. The most troublesome portion of the present air-cooled engine is the valve port, from crankcase to valve such as for the intake system, there, both in valve gear type and in durability of the present valve gear. Engine life will increase as a result both of improved construction and of more experienced handling by operators and service men. No marked improvement in efficiency or substantial weight reduction can be expected this year.

4. It is possible but not desirable to increase compression ratio with the base fuel now in use. The advantages

to be gained do not measure up to the grief which less than ideal designs.

5. I see no prospect of marked improvement in efficiency or reduction in frontal area due to the general commercial use of higher grade fuels. The fuel companies have made remarkable progress in the manufacture and distribution of high grade aviation gasoline and the Avco and Pratt have attained extraordinary engine performance on special fuels, but there are too many hazards in that direction to expect such commercial progress this next year.

6. The compression engine engine will have a long road to level. It shall be expected to see any given engine into an airplane engine territory in the next four years, and then only by the two-stroke cycle Diesel.

7. There is at present a decided trend toward greater power and consequently probably to larger number of cylinders. This trend may be stemmed temporarily by the realization that more frequent flights over than larger airplanes in the immediate need of air transportation. Therefore while W or X engines are likely to be needed later, they probably will not be numerous this year. I do not see any new design low radial.

8. Some of the new materials likely to be used this year are magnesium castings and forgings, replacing aluminum castings and forgings, aluminum Company No. 123, or similar low expansion aluminum alloys; nickel steel (high expansion iron) in connection with aluminum castings, and spinners joints, Nitralloy for shafts, cylinder barrels, etc., forged stainless steels; high lead bronze for bearings, bearings, grades; Carbonyl for protection tools.

9, 10, 11. The present engine mounting is about all that can be expected in the coming year. Use power plant sections, including all power plant equipment except controls and fuel tanks, and replaceable easily as units, are likely to be developed later. Simplification of plumbing, directly fuel lines is especially needed. Engine cooling is now primarily furnished by engine builders. Gradual substitution of accessory couplings and locations is to be expected.

Better Accessories—Better Reliability, Better Co-operation of Airplane and Engine Designer

By HENRY M. MULLINIX

*Former Chief of Post-Test Service,
Army Air Corps of Aviation*

AN OVERVIEW of aircraft engine is a permanent feature of design. In the past, the engine has been the least vulnerable of air-cooled engines, the special limitations on airplane design are such that liquid-cooled engines are out of the question. These are definite fields for the liquid-cooled power plants, however, along with such as (a) aircraft for special purposes such as racing, etc., and (b) modifications demanding inherent needs of high power.

It seems that practical limits of air-cooled cylinder sizes have been reached. Larger cylinders may be employed at reduced loads mean effective pressures, or engines of greater power may be associated with more cylinders, but when cylinder power or torque is increased it seems better to resort to liquid-cooled cylinders of larger size.

In further development of shaft air-cooled types it is probable that inline or Vee engines may gain in favor. There is little to recommend these types in comparison with the radials for the intermediate sizes, but the X or V arrangements offer some advantages in turbine or turbine-cylinder units.

The greatest improvements in engine performance anticipated in the near future are refinement in details and improvements in accessories. Accessories susceptible of development or improvement include fuel pumps and meters, oil coolers, water pumps, water, oil, and oil, power plant accessories, carburetors, and air cleaners. Cooling improvements already indicated should be adapted and applied.

Reliability will be improved, but not far between overhaul. The 40-hour period now generally assumed for overhaul should be just a rule, not a hard and fast condition. Higher speeds and heavier loads which may be required in future aircraft operations may force some reduction in time between overhauls.

Minor savings in power plant weights are possible at some increase in cost of maintenance. Reduction of weight may be attained by design modifications, but considerable savings do not seem possible without reduction of safety factors unless through employment of improved materials. Better ferrous alloys and commercial availability of lighter non-ferrous materials, such as magnesium alloys, beryllium alloys, and so on, will be better technique in employing such materials, should permit material savings in weight per horsepower.

Material increases in present design practice as regards compression ratios while employing the present basic fuels do not seem feasible. Even though fuels of better anti-knock characteristics were available, the permanent increase in compression ratios would entail operating difficulties out of proportion to the advantages derived. Increase of compression ratio and brake mean effective pressures to obtain desired weight and fuel economy involve reduction of air density and volume, thereby making more expensive, to special purposes. There is a distinct field for employment of "boosted" engines, i.e., engines supercharged above atmospheric pressures at sea level, in high altitude and other specialized types of aircraft. For these engines special fuels are required.

There is definite need for improving fuels, as governed by specifications, with a view particularly to ensuring uniformity of anti-knock and other qualities. No marked increase in the anti-knock quality of the fuels should be required for existing engines, but fuels should be brought up to the standard set by the better grades.

There is not any immediate prospect of employment on a large scale of the compressed-air-type type of engine in aircraft practice. The advantages of compression engines, including reduced fuel consumption, efficient use of electrical apparatus and heat of radio interference, elimination of carburetor problems, and other benefits less evident, would more than outweigh the difficulties encountered in metering and injecting measured quantities of fuel at the proper pressure. Although the Diesel cycle engine suffers some comparison with the Otto cycle engine in flexibility there seems to be a definite field for employment of Diesels and a gradual expansion of their use may be predicted.

The present type of engine mounting is fairly satisfactory although there is room for standardization in the matter of mounting of different engine, and location

of the piping, fittings, controls, and other accessories. There is a great need for improvement in accessory installations, particularly carburetor air heaters, air cleaners, and miscellaneous items. Some arrangements of accessories may be made by the engine designers but any changes in such matters must be gradual. "Flashing" may be improved by standardization of fittings, and such expedients as employment of short lengths of flexible metallic tubing where great flexibility at resistance to vibration is needed. A great deal of research effort has been expended upon development of fuel pumps, valves, nozzles, and mechanical fittings, but further improvements are needed.

It has been suggested that engine builders should produce complete power plants, including standard accessories, coolers, oil tanks and other accessories. There seems to be a need for more information regarding cylinder barrel operating temperatures, permissible oil temperatures and engine cooling designs, including shutters and other controlling devices. These are problems for engine builders, since faulty installation may impair engine performance, or life, or both. The connection between complete airplane designs and cooling design, of tank arrangement and other power plant details is so close, however, that it seems best to leave final details to aircraft designers and builders as heretofore but to make additional information available in the future. Building of interchangeable and power plant sections for particular models of aircraft is desirable and in air transport and other aircraft sections readily detachable and interchangeable unit power plants should be of material assistance to maintenance engineers.

• • •

Liquid-Cooled Engines Supreme for High Powers—Diesel Development Final— Get Better Fuel and Pay the Price

By JOHN H. GIESSE

Chief Engineer, Curtiss-Wright Corp.

THE liquid-cooled engine will undoubtedly require substantial favor within the next two years. In the higher power units it will entirely supplant direct air-cooled engines. In the medium and low power classes it will probably share the business with the direct air-cooled radial engine.

2. The air-cooled engines will undoubtedly continue to be predominantly radial. I expect the direct-cooled inline V and X engines to be entirely supplanted by liquid-cooled engines of the same form.

3. I do not look forward to any very substantial reductions in weight per horsepower and would not be at all surprised at increases in the future. I do expect substantial increases in length between overhauls, and reductions in fuel consumption.

There will be a gradual increase in the appreciation of the relative importance of durability and low fuel consumption in comparison with specific power. It is possible to increase compression ratios with fuels at present available, at the expense of power output

John H. Giesse

per cubic inch displacement. Because of the importance of fuel consumption I expect a gradual trend toward the use of lower mean effective pressures and higher compression ratios.

3 I am very much in favor of attaining higher loads for aviation engines. Because of the cost of carrying the gasoline in the plane a very much more substantial increase in cost per gallon for non-detaching characteristics is warranted in aviation gasoline than is warranted in automobile gasoline. Just as soon as such a gasoline is made generally available the airplane engine manufacturers can provide engines which will not only give increased plane performance but will decrease substantially the cost per mile per pound of fuel load.

4 The true Diesel cycle, by which I mean a cycle in which the fuel is burned at constant pressure, will undoubtedly play an important part in the future development of aviation. So far as engines are concerned, it is the most important advance which can be foreseen at the present time. The time which will be required for this development depends entirely upon the amount of funds made available for development work. I am firmly convinced that the Diesel engine in the future will not only maintain the advantages of Diesel engines as they are now known, but will also be lighter in pounds per horsepower than the present Otto engines.

5 I do not expect any substantial increase in cylinder arrangement. Neither the double-row radial nor the X engine can be considered as innovations as they have already been used. However, I am no fanatic future for the double-row radial but I do see a future for X engines with liquid cooling.

6 As in years past, there undoubtedly will be improvements in materials. Increased use of magnesium may be expected when the airplane engineer sufficiently appreciates the value of weight saving to pay the premiums required.

7 I do not see any particular advantage in the so-called high compression as such. A four point mounting would be relatively expensive. However, any mounting arrangement which decreases accessibility, however simple it may be, is not warranted.

8 I rather expect considerable improvements in accessory installation. Provision of a through drive on accessories would simplify the engine designer's problem. As examples of this, provision for driving the tachometer from the end of the crankshaft would in many cases eliminate some gearing, as would also the design of a generator which could be used in the lower shaft for driving the oil pump.

9 I have always contended that the engine manufacturer should provide the engine without lack to the fuel tank.

Magnesium Crankcases—Anti-knock Fuels—Better "Plumbing"?

By G. FARETTE TAYLOR

Professor of Aeronautical Engineering
Massachusetts Institute of Technology

IT IS ALWAYS dangerous to make predictions for the future, but I will endeavor to answer your questions as best I can.

1 I believe that the liquid-cooled engine will always remain a useful phase in aeronautical application particularly for military and for lighter-than-air work.

2 I believe that air-cooled engines will continue to be predominantly radial for the next year or so, although the proportions of H-ree and V type engines will show a decided increase.

3 I do not expect any radical improvements in engine performance in the near future. There should be a gradual but slow trend toward increased reliability and reduced weight per horse power.

4 I do not understand what is meant by "base" fuel. It is perfectly possible to improve the anti-detonation qualities of gasoline substantially, in which case compression ratios can be increased.

5 I am certainly in favor of a reasonable anti-detonation requirement in our fuel specifications for aviation gasoline. If the best aviation gasoline now available were taken as a standard it would show some increase in present compressive ratios, which are limited by the worst fuel which they are likely to encounter at the present time.

6 I believe that the compression ignition engine will continue to remain in the experimental stage during the year 1933. I should expect its first really practical application to be in light-tandem-air craft.

7 Double-row radial engines are already with us, namely the Curtiss Challenger, the Brewster, the Anson, and in England, the Armstrong Siddeley. I do not expect that 1933 will show any very great increase in the number of such engines, or will find the X engine in general use.

8 Magnesium alloys are in fairly general use in crankcases in Europe, and I should hope that this development would reach the United States in the near future. Magnesium is not suitable for cylinder heads, and I do not think that American manufacturers will put up with the excessive maintenance expenses of forged cylinder heads to any great extent.

9 I am never satisfied with any engineering structure, unless improvement is always possible. This applies to engine mountings as well as everything else.

10 I have been hoping for real improvements in "plumbing" for a number of years. At the present time this large still seems to be in an error.

11 There is already a decided trend toward the simplifying by the engine manufacturers of most of the engine accessories, including such items as the exhaust system and part of the cooling system.

In general, I look forward to the introduction of a definite antiskid value in fuel specifications to be one of the most important steps to be expected within the near future. The development of the compression ignition engine is being pushed by so many competent laboratories and individuals that I expect rather rapid progress along this line. Another very important development which should be completed within a reasonable time, is the National Advisory Committee research on the proper relation of the propeller with respect to an airplane wing and oil-cooled engine installation. This may have an important effect on the trend of engine design. Further improvement in cooling for radial engines seems perfectly possible, and may reasonably be expected if the National Advisory Committee continues its researches along this line in their large wind tunnel.

Another important development which may be looked forward to is more definite information on the value of propeller reduction gearing for various types of airplanes. The answer to this question, of course, might have a very distinct effect on engine design.

Air or Liquid Cooling?—Electrical Fuel Pumps

By LIEUT. COLONEL C. G. MCCOBB, U.S.N.

Nest Abbott Factory

IT SEEMS PROBABLE that much work will be done during the current year about the lines of high temperature liquid cooling, following the trend of Army and Navy tests which show a considerably increased fuel economy and a low percentage of fuel lost rejection due to its application. It will require more than a year's test, however, to develop production engines on this principle.

A last note of the relative advantages of the average of several air-cooled engines as compared to some pressure cooled engines is appended as being of possible interest.

	A	L
Specific Dry Weight	1	1
Total Weight at Power Plant	1	1
Aerodynamic Loss	1	1
Number of Parts	1	1
Ease of Mounting and Cooling	1	1
Weight of Radiator	1	1
Cooling Required by Use of High Pressure	1	1
Avoids Plumbing Obstacles	1	1
Thermal Efficiency	1	1
Mechanical Efficiency	1	1
Valveless Efficiency	1	1
Avoids Valve Problems Overhaul	1	1
Accounting for Interest	1	1
Real Crankshaft Load Reduction	1	1
Weight of Fuel and Plumbing	1	1
Elimination of Cylinder Head	1	1
Elimination of Compression Ratio	1	1

2 While the present system of combustion of fuel is in use, the superior disposition of weight in the radial engine added to its cooling, covering and installation advantages will probably keep it in position favorably contrasting to find the Vee, in-line or X types of cylinder arrangement as a development of the future. The air-cooled engine is reported as being in use with some degree of success.

3 Improvements anticipated are along the lines of application of solid fuel injection, compression ignition and use of higher cylinder temperatures. Some hope may be held out for the development of a 1000° C. and 7000° C. engine and for a rapid change in head design which will permit a safe increase in horsepower per cylinder in air-cooled engines above the present limits. Life between overhauls increases with the above, and steady progress of development and development of materials, and no radical advance is to be expected. The same remark applies to specific weight.

4 Improvements in fuel during the past two years indicate a possibility of going to higher compression ratios with modern liquid-cooled fuels by use of the heavier fuels in the present boiling range show or blended with the lighter paraffins, both types tending to suppress detonation, but probably requiring special fuel tanks for extreme applications.

5 Higher standard and uniform fuel for aircraft growth by refinery distillation specifications is currently recommended. Test methods will have to be standardized.

6 The use of compression ignition, in due time, appears to be assured, but increase in weights above those of present Otto cycle engines, to assure reliability, must be expected.

7 It is questionable that the desirability of mounting of engines in wings, using wing surface materials, may

bring about development of a horizontal opposed type of cylinder arrangement.

8 No change of materials of construction is anticipated, although refinement of methods for working what we have contains.

9 Present types of engine mounting, excepting most types of liquid mounting of air-cooled engines as far as design, appear to be satisfactory.

10 Removal of fuel pumps from the engines and substitution of electrical pumps in large ship installations appears logical. Further advances in the matter of tubing material are also indicated. A trend toward complexity of plumbing is shown by the number of diameters, bores, and filters of various descriptions now on the market.

11 The present system of design should be continued somewhat as power plants are far from the point of standardization and cooling is still in the experimental stage.

The last year brought fairly very little in the nature of radical change or improvement in Naval aviation power plants, but did bring an encouraging improvement in government contract bids.

Diesel is Coming—Special Fuels May Be Too Expensive—Radials Still Hold the Field

By L. M. WOOLSON

Associated Engineer, Packard Motor Car Co.

MY OWN REACTIONS to the very interesting questions which you have presented are as follows:

1 Explaining somewhat is far from being crystallized on the question of engine cooling. In the larger size engines there is so much that water-cooling or liquid-cooling is here to stay for some time in the near future. In the smaller size it is my opinion that troubles with water-cooled engines due to plumbing have been grossly exaggerated. On the other hand, in the smaller powered engines there is no question that direct air-cooling is preferable.

2 Having witnessed developments I would expect the radial air-cooled engine to maintain its leadership.

3 I am convinced that greater reliability, decrease in cost and an increased ease of maintenance are far more important questions than any minor reductions in weight per horsepower.

4 I believe that gasoline aircraft engines today are as high compression ratios as it is feasible to use, fuel limitations being considered.

5 Any improvements in fuels which can be brought about without perceptible increase in cost are highly desirable, but except for military purposes I do not believe that any substantial increase in cost is warranted to obtain the results mentioned.

6 There is no question that the compression ignition aircraft engine will in time offer severe competition to the gasoline engine. There are, however, many basic problems to be solved for the solution of which there exists no precedent.

7 There is no reason to believe that we have exhausted

L. M. Woolson

Equip Lindbergh's Plane With Dismountable Top

COLONEL LINDBERGH, SEATED in his Lockheed Stratus, shown as it appears with the detachable cold-weather covering recently developed as protection against the elements. A non-dismountable transport configuration is used in the device which can be easily removed when the weather is fair.

House Reports Budget

The committee is also concerned with the problem of the design of aircraft upon the state of structural strength of aircraft under stress. The committee is also concerned with the problem of the design of aircraft upon the state of structural strength of aircraft under stress.

Personnel

At the present time the membership of the National Advisory Committee for Aeronautics is as follows: Joseph A. Ames, Ph.D., chairman, president of the Johns Hopkins University, Baltimore, Md.; David M. Taylor, D. Eng., vice-chairman, Washington D. C.; Charles E. Abbott, Sr., D. Eng., secretary, Washington D. C.; George K. Burgess, Ph.D., director Bureau of Standards, Washington, D. C.; William P. Doolittle, Ph.D., professor, University of Michigan, Ann Arbor, Mich.; and John D. Cockcroft, Ph.D., professor, University of Cambridge, England.

Coast Force Control
Question Still Unsettled

WASHINGTON (n.c.)—No final decision of the different committees before the Army and Navy on the question of coastal defense still have been reached, it was indicated in a recent statement by the Secretary of War. Secretary Denney called attention to the fact that the Army has been in charge of coastal defense operations for 150 years and the War Department has no intention of relinquishing its control over this part of the nation's defense.

Meanwhile, it is intimated that Navy officials are adopting an interpretation of these responsibilities that would afford them control over all operations, whether marine or aeronautical. A tentative decision has also been made in connection with the naval air shore stations. Members of the House Committee in charge of departmental responsibilities believe that the best method of solving the problem of air defense would be to create an air corps independent of both Army and Navy.

In this connection, the House Committee on the Judiciary, chairman of the committee on expenditures in connection with the military, is making it difficult to have introduced in the Senate a bill proposing the creation of an independent air corps. The bill is pending in the committee on the military, chairman of the committee on expenditures in connection with the military, is making it difficult to have introduced in the Senate a bill proposing the creation of an independent air corps. The bill is pending in the committee on the military, chairman of the committee on expenditures in connection with the military, is making it difficult to have introduced in the Senate a bill proposing the creation of an independent air corps.

Three Mohawk Planes to Tour

MINNEAPOLIS (n.c.)—An extensive demonstration tour will be made through the northwest by A-8, K-8, and P-8, three of the new Mohawk aircraft. The tour will be made through the northwest by A-8, K-8, and P-8, three of the new Mohawk aircraft. The tour will be made through the northwest by A-8, K-8, and P-8, three of the new Mohawk aircraft. The tour will be made through the northwest by A-8, K-8, and P-8, three of the new Mohawk aircraft.

Aviation Credit Reports Earnings

NEW YORK (n.c.)—After deducting expenses and federal taxes, the Aviation Credit Corp. reported a net income of \$200,000 for the year ending December 31. The 1950-51 report shows a net income of \$200,000 for the year ending December 31. The 1950-51 report shows a net income of \$200,000 for the year ending December 31.

Appoint Show Photographer

ST. LOUIS (n.c.)—Wages Photo Service, Inc., St. Louis, Mo., has been appointed official photographer for the International Airwork Exposition of the Aeronautical Chamber of Commerce, Feb. 13-23.

Detroit Will Exhibit
75 Planes of 34 Makers

Detroit (n.c.)—Twenty-five airplane manufacturers, presenting an array of 75 different models, and 30 groups of aircraft designers, are planning to enter the list for the Third Annual Air America Aircraft Show, which is to be held in Detroit, April 5-12, in a new \$1,000,000 hangar and exhibition building on the municipal airport.

The announcement by Ray Cooper, show manager, at a luncheon with the statement that practically all of the plane exhibitors will bring demonstrators to Detroit in the week following this week will set a pace for about 100-150 different aircraft on display.

While an army of workmen is putting the finishing touches on the exhibition building located in the large structure of its kind in the country, show headquarters in the Detroit Board of Commerce are endeavoring to find additional exhibitors to take care of a shortage in which they had a good announcement with each Jan. 1, that the show was "sold out." It is intimated that a smaller hangar may be leased as an annex.

The Detroit exhibition will be cosponsored by the Detroit Board of Commerce with the sanction of the Aeronautical Chamber of Commerce. Edwin S. Davis, president of D.B.C., leads a group of better citizens, including the experience, the vice-chairman of which was William B. Mayo, chief of the Detroit Board of Commerce, and William E. Metzger, a capitalist, formerly connected with the automobile industry and now collector of aviation.

Proposes Mass Arrangements

BOSTON (n.c.)—Rep. Harold E. Duffie, sponsor of the bill to provide an airplane for the state aviation authority, has introduced three amendments to the same aviation law. One requires that the majority of major vehicles be restricted to all military and federal planes in use in operation. The second amendment requires that the majority of major vehicles be restricted to all military and federal planes in use in operation. The second amendment requires that the majority of major vehicles be restricted to all military and federal planes in use in operation.

Deposits Enforce Air Laws

SAN FRANCISCO (n.c.)—The central coast council of the California State Chamber of Commerce has adopted a plan whereby the state of such county of the state designate one deputy with the authority to enforce the state and federal laws governing air navigation.

Roadways Purchases Spurious

TULSA (n.c.)—Two spurious plans have been purchased by the Oklahoma government, a report states, and there is a tentative order for a new car to be equipped with a new one. The plans were the result of a sale trip made by E. M. Gandy to Mexico, Guatemala, El Salvador, and Honduras.

... And a Berth, Too

MANHATTAN, N.Y. (n.c.)—The new New York City Hall recently mentioned. Filled every plan in the upper level had some way to be a full-scale hotel.

N. Y. Legion Show Under Way

NEW YORK (n.c.)—The second annual American Legion air show opened here Friday, Feb. 6, with some of the most spectacular military, and historical interest on display. Probably the most interesting attraction was the new 15-engineer (one-engine) aircraft, which was the first of the New York show will appear in the state since Air-2000-20.

Central Alloy Speeds Up Plans

KASHIHLON (n.c.)—Only 10 miles, instead of 40 is now required for the new alloy of aluminum, which is being developed by the company's engineering and metallurgical departments, according to a statement of the Central Alloy Steel Corp. This new alloy is being operated in the Central Alloy, plant.

Speakers Banned for Minnesota

MINNEAPOLIS (n.c.)—An aviation speakers bureau has been organized and the Central Alloy Steel Corp. has been organized in the Twin Cities.

Brazion Measure Asks
Accident Data Since '26

WASHINGTON (n.c.)—Further indication that Congress desires a change in the present aviation accident reporting policy was made by the Department of Commerce in a recent statement. The Secretary of Commerce to Kansas the Senate with full information regarding each accident, which has been required since May 30, 1926. The Secretary of Commerce also is asked to advise the Senate of the names of the persons involved in the accidents during this period, whether they were pilots or passengers, to specify the date and place of the accident, the make and model of the plane, and to report the complete findings of the department as to primary and contributing causes of the accidents.

A number of other Senators have expressed interest in the aviation problem. Senator Charles McNary, of Oregon, has introduced a bill to require a report of approval from all sections of the country after he had introduced a measure requiring the Secretary of Commerce to report to the Senate the findings on a particular accident in which he was involved. At the Senate, McNary's measure, it only needs to be passed by that body and no action by the House is necessary. It has been referred to the Senate Commerce Committee.

Manufacture Continued

Senator McNary has announced his intention of making public the information from the Commerce Department as to the results of the investigation of each accident. He has also announced that he will make a public statement of the results of the investigation of each accident. He has also announced that he will make a public statement of the results of the investigation of each accident. He has also announced that he will make a public statement of the results of the investigation of each accident.

Formella Gibson Inactively

Through an error in set up, the speedometer in the top of the second column, page 236, in the February issue of "The Encyclopedia of Aviation," Competition Team and the Central Alloy Steel Corp. has been incorrectly stated. The correct reading is:

$$P_1 = P_2 + P_3 - P_4$$

It should have read:

$$P_1 = P_2 + P_3 - P_4$$

FOR THE SAFETY OF PASSENGERS

CARRYING passengers adds to your responsibility—makes it even more necessary to reduce hazards by every available means. That's why so many transport companies rely on T-P to keep the engines running smoothly.

T-P Aero Motor Lubricating Oil is new—the latest development in scientific lubrication. They have been tested and approved by leading manufacturers of airplane engines and by many leading pilots. They are straight-run oils, not blended or compounded, produced from pure, paraffine-base crude by a process for which patents are pending.

This process has marked ad-

vantages over other methods. It removes all the paraffine wax, while preserving all the lubricating bodies in the crude. Elimination of the wax is responsible for its low cold test.

In terms of performance this means uniform viscosity at all working temperatures, minimum carbon deposit and ignition trouble from fouled spark plugs, easy cold starting, immediate oil pressure, perfect lubrication winter and summer, on the ground or at high altitudes—a maximum of safe flying hours.

A handsome, practical Pilot's Log Book sent free on request.

Meyrowitz presents the 1930 masterpiece of eye protection

LUXOR GOGGLES No. 8

WITH WIDE FLARING FEATHER-EDGE CUSHIONS

THE research laboratories of Meyrowitz have perfected Luxor Goggles No. 8—a distinct contribution to the safety of piloting aircraft. These goggles are constructed to give the pilot a wider range of true vision, a higher degree of fit and comfort, and eliminate pressure, slippage, headsets, discomfort, fogging or sweating and air leakage.

THE MAJOR FEATURES (as pictured by J. J. Farnley)

WIDE FLARING FEATHER-EDGE CUSHIONS

—made of soft resilient sponge rubber—wide, flat and tapered, covering and protecting the most sensitive parts of the face without pressure. Fits almost as though you had no goggles on at all—no more headsets or straps, no slippage at high speed. The special nose section is a complete revolution (see inset photo below).

DURALUMIN FRAMES—weigh half as much, give greater strength. Durable and will not tarnish or corrode.

MICRO-ADJUSTABLE BRIDGE—with clutch type lock, quickly adjustable and maintaining perfect horizontal alignment under all conditions.

NON-FOGGING VENTILATING CIRCUIT—most perfect ventilating system for goggles. Air stream enters at bottom, is directed against lenses and exhausts at top. No air currents can touch the eyes. Lenses will not fog or sweat under most trying conditions.

OPTICALLY GROUND LENSES—ground and polished to order Army or Navy specifications—optically sound as mirrors. Wide vision with true optical focus.

See the new Luxor Goggle No. 8 at the International Aircraft Show in St. Louis. Try again, we know they automatically fit your face—any face, without adjustment. Once you fly with them, you'll never be satisfied with any other goggles. Luxor Goggles are on sale at optical and sporting goods stores, flying fields and airports. Write for special order permission.

E. B. Meyrowitz
Optical Engineer
Buffalo, New York

Send for
catalogue

520 Fifth Ave., Dept. B., New York

The clear, optically ground lenses of the goggles give a wide range of vision and true optical focus. The lenses are polished to order Army or Navy specifications—optically sound as mirrors. Wide vision with true optical focus.

LUXOR GOGGLES

FOR AEROPLANE MOTORS

Greater Accuracy and Speed on Aeroplane Valve Work

PRECISION work in refitting valve seats on aeroplane motors is made easy with the **Stoux** method. This **Stoux** reaming outfit includes a special **Stoux Pilot Stem**, **Feed Screw**, **Feed Screw Body**, and **T Socket Handle**. When the **Feed** is screwed up it brings the reamer against the valve seat. A simple, positive arrangement keeps the reamer teeth beneath the surface of the metal, preventing the reamer from sliding over the ground surface.

Stoux Aeroplane Reamers are made of a special alloy tool steel which stands up and holds its cutting edge in the most work of cutting the beveled valve seats used on most aeroplane motors. They are also made left handed so the tool can be turned to the right. Cutting resistance has been reduced by eliminating some of the cutting edges. Made in 45° finishing and roughing, 15° screwing in finishing type and 75° screwing in finishing type.

VALVE SEAT REAMERS

FIRE — AN INCIDENT OR A DISASTER ?

Ruts? Snow? Sand?

The FOAMITE WIDEWAY Goes Through

Crushing planes don't always land at convenient points. And when fire breaks out it's often hard going to get to pilot and plane. Minutes, seconds count! Then is the time when the new FOAMITE Wideaway engine jupernavates its way over all obstacles. It gets there!

The FOAMITE Wideaway is particularly adapted to your

needs. Its wide 8 inch tires with roller bearings permit easy pulling over soft, sticky or rutty ground, across tracks. And the construction of the Wideaway is rugged enough to stand the gaff!

The FOAMITE Wideaway meters its 40 gallons of chemical solutions to produce Fire-

foam, which smothers the fire, cuts down heat and makes rescue work easy.

For complete information on American LaFrance and Foamite Service, or for a copy of our booklet on the FOAMITE Wideaway engine, write American LaFrance and Foamite Corporation, Department T-29, Elmhurst, New York. Offices in all principal cities.

LA FRANCE AND FOAMITE PROTECTION

AN ENGINEERING SERVICE

AGAINST FIRE

ANOTHER MANUFACTURER IN THE AVIATION INDUSTRY THAT USES SKF BEARINGS

CURTISS AEROPLANE & MOTOR COMPANY, INC.

ON THE CURTISS TANAGER PRIZE WINNER 96 SKF BEARINGS MADE GOOD

ON the Curtiss Tanager, winner of the \$100,000 prize in the Guggenheim Safe Aircraft Competition, ninety-six SKF Ball Bearings are used. This was the only entry to pass the eighteen qualifying tests there, fore making it unnecessary to hold the final competitive tests. SKF takes pride in the part its products played in meeting the extremely severe stipulations of the qualifying conditions.

Mr. Robert B. Osborn, the design engineer, says, "Four SKF Self-Aligning Ball Bearings were on the new Curtiss ailerons, one of the outstanding features of the ship. Ninety-two SKF Bearings were used in the automatic slot installation. Before using these bearings to carry the automatic slot loads they were tested under a load of 1250 pounds... and rolled easily with no damage to the balls or races."

SKF INDUSTRIES, INC., 40 East 31st Street, New York, N. Y.

EQUIPPED WITH THE HIGHEST PRICED BEARING IN THE WORLD

Means just this

SKF
Ball and Roller Bearings

That the manufacturers whose product is illustrated above prefer to pay more for their bearings and then for servicing or replacing them. They prefer to pay a higher price in the beginning than many times this higher price in the end. And, finally, they preferred to continue by using SKF bearings because they are made to do their job, not to fix a price tag.

FOR FUEL AND OIL LINES Our Latest Contribution to THE AERONAUTICAL INDUSTRY

This new connection is our answer to the challenge of the Aeronautical Engineers for a Leakproof Copper and Aluminum tubing connection that will resist vibration.

In development covers two years of over 600 series of vibration tests.

Let us tell you more about it at our booth at the coming International Aircraft Exposition at

ST. LOUIS, FEB. 15 to 23, 1930

Adopted by the Sky Specialties Corporation of Detroit for the Heywood Starter after conclusive tests in favor of the Hi-Duty.

To Dominate

its field in 1930

beyond a question of doubt

MONO-AIRCRAFT Offers

... a new two place, cabin monoplane with a top speed in excess of 120 miles an hour (—yet with a fuel cost less than 1½ cents per mile).

... new smartness in appearance, greater comfort, improved vision and incomparable stability.

... a new 90 horse-power engine, second to none in the world for dependability, accessibility, simplicity and economical maintenance. (We will supply a kit of five cylinder barrels, pistons with rings fitted, valve guides, rocker arm bushings, gaskets and spark plugs for \$75.00 list.)

... complete accessories contributing to added safety such as brakes, steel propeller, parachute pack seats, air speed indicator and the best instruments money will buy.

... a price as usual below anything else in the field.

*Nineteen Thirty Will Be a
Mono-Aircraft Year*

Full information is yours for the asking.

MONO-AIRCRAFT CORPORATION
MOLINE, ILLINOIS

Compact Easily Installed Accessible

Western Electric Radio Telephone Receiver designed for maximum convenience

Western Electric's radio telephone receiver may be installed in any part of the plane, with remote tuning and volume controls conveniently placed on the pilot's instrument panel. Ease of operation is assured under all flying conditions.

The receiving set (measuring 9½" x 12½" x 6" and weighing but 37 pounds) may be removed from the plane for inspection, transferred to another plane or used on the ground by simply loosening four wing nuts. All parts are readily accessible. Power supply by dynamo or operating from plane battery or wind driven generator.

With the airplane radio telephone receiver the pilot "fits the machine" when darkness, fog or clouds obscure his view of the ground. He receives instructions and weather reports from airports along his route, enabling him to make decisions of vital importance based on accurate information.

And with Western Electric transmitting apparatus also installed in his ship he has communication facilities which enable him to make contact with dispatchers or other pilots in flight. For full details write to Western Electric Company, Department 244A, 125 Broadway, New York, N. Y.

The FOUNTAIN of YOUTH FINALLY LOCATED

71 year old
executive
succeeds
where
others
have
failed

Mr. Charles Fox

Mr. Charles Fox, a Vice-President of The Black & Decker Mfg. Co., advises that he has found Ponce de Leon's "Fountain of Youth," for which intrepid explorers have searched for hundreds of years. Mr. Fox says that every one who has been looking for the famous fountain on the ground, whereas he has discovered it to be in the air.

Mr. Fox left Baltimore in the Black & Decker "ship" in January, intending to make a brief "stop" in Richmond, Va. It was his first trip by plane and was in the nature of an experiment. The plane was scheduled to roll at 36 airports in a forty day swing through Virginia, North Carolina, South Carolina, Georgia, Florida, Louisiana, Arkansas, Alabama and Tennessee, for contact and investigation work in connection

with the supplying of electric tools and equipment developed to meet the specialized requirements of The Industry.

Instead of a two-hour flight as planned, Mr. Fox stayed with the "ship" for the entire trip.

(In the course of the trip this "ship" won several prizes at the Miami Air Meet.)

The Black & Decker Mfg. Co. takes this opportunity of expressing appreciation of the hearty reception accorded the plane everywhere it has sailed, and for the enthusiasm in operation exhibited by its representation.

at the International
Aircraft Exposition
in St. Louis - Feb. 15 - 23

Curtis Compressor, Model M, 100 C.F.M. with compressed air to 200 lbs. G. and motor.

Curtis Air Hose, suitable from 15 lbs. to 100 lbs.

Curtis Air Hoist, Crane and Trolley lift to 100 lbs. and 15 ft. in lifting.

Curtis Portable Air Tank. For taking air out to a place away from the usual source of supply.

JUST as compressed air has long helped automotive industry, it is now helping the aviation industry to get greater production at low cost.

A visit to the Curtis exhibit of compressed air equipment at the International will be of inestimable value to executives who want to learn more about

How compressed air speeds up airplane production and servicing

CURTIS TIMKEN EQUIPPED COMPRESSORS—providing air for spray painting, spraying dope on the wings, tire inflation, charging shock absorbers, spray cleaning engines, spraying of grease solvent or paint removers, air drying of parts dipped in cleaning solutions, blowing out dust, chips, etc. at benches and drill presses, power for operating air hoists, trolleys, pneumatic drills, sand blasts, pneumatic water systems, etc.

CURTIS AIR HOISTS—Power hoists at little more than the cost of chain blocks. Used with a Curtis I-Beam Trolley or Crane, they can serve a wide floor area. Used for lifting engines out of fuselages, mounting engines, and other parts, and many other purposes where a combination of power, speed and accuracy is a factor of economy. Because there are no delicate mechanisms, even unskilled laborers can operate Curtis Hoists without danger of throwing them out of commission.

CURTIS AIR TANKS—Portable tanks for taking air out to a place away from the usual source of supply. Stationary tanks for use with compressor unit in the shop, also separate tanks for mounting on service trucks.

The Curtis Pneumatic Machinery Co. was founded in 1894 and has since then been a leader in the development of compressed air equipment. Its products are used in every branch of industry and commerce to produce maximum efficiency and economy in production and service.

Brownback C400

TIGER

SMOOTH, VIBRATIONLESS POWER

DEPARTMENT OF COMMERCE APPROVED TYPE CERTIFICATE No. 33

Tight Light Manufacturing and Foundry Company announces the Brownback "TIGER" . . . a new aircraft engine which delivers smooth, freedom vibrationless power for a greater number of hours in the air than has hitherto been possible.

The first cost is low—the maintenance cost is almost unbelievably small. Complete simplicity of construction, the accessibility of all parts and the ease of servicing reduce together hours and repair costs to the very minimum. The Brownback "TIGER" will break all records for economical operation and sustained service over long periods of time.

**Correct design
and sturdy construction
mean more flying hours
at lower cost**

It develops 115 h.p. at an extremely low r.p.m., reducing vibration and engine-stress. This is a particularly serviceable engine for training or instruction planes. Weight is less than 3 lbs. per h.p.

Write for descriptive literature which contains a complete description of the distinctive design of the "TIGER" engine. A "TIGER" engine has been installed in our Demonstration Plane and you will be glad to arrange a thorough demonstration of this revolutionary aircraft engine in the air. See us at the International Airport Show, 911 Union Avenue, National Division, LIGHT MANUFACTURING & FOUNDRY CO., Farmstead, Pa.

Where minutes mean miles and miles mean life or death!

THE one place in the world you might think Time would be unimportant is at the South Pole. But that is not true. Byrd had to know the exact time to navigate properly. That's why 60 Hamiltons were selected as the official watches of the Byrd Antarctic Expedition—and four of them charted the Expedition plane across the icy wastes of the Pole itself.

Barring their winter trappings—special felt-lined extra cases—these Hamiltons are identically the same as the watches that time our country's fastest trains . . . and snuggle in the pockets of our most successful business chiefs.

Whether it is at the South Pole, the North Pole, with the country's air-mail pilots, in your pocket or on your wrist, every Hamilton is an accurate timepiece you would be proud to own.

Let us send you "The Timekeeper," an unusual little booklet, beautifully illustrated, showing a complete assortment of beautiful new Hamilton models. Address: Hamilton Watch Company, American manufacturers of high-grade watches, 901 Columbia Avenue, Lancaster, Peoria, U. S. A.

Hamilton *The Watch of Railroad Accuracy*

Above—The "Marathon," Model C. The dial of swirling silver has round elements of solid gold and solid gold hands. In 15K white or green gold with 25 jewels, \$130.

Complete Fire Protection in below-zero weather!

An absolute necessity for Hangars, Airports,
and Airplane Factories

BADGER'S Non-Freeze 40 Gal. Fire Engine

BADGER
offers Fire
Protection for
every need

Protects planes, oil and gas tanks, hangars, etc. from fire. Also used for fire protection in all cases where fire is a danger. Also used for fire protection in all cases where fire is a danger.

(Left) 40 gal. hand, or motor, or pump, or sprayer, or any other type of fire engine. (Right) 40 gal. hand, or motor, or pump, or sprayer, or any other type of fire engine.

All Badger Extinguishers are approved and recommended for use by the Underwriters Laboratories, and the Factory Mutuals.

BADGER'S Non-Freeze Fire Engine handles the fearful extra hazard of winter fires. It has passed every test of the Underwriters Laboratories and Factory Mutuals, and is recommended by them for use. It's always on the job, in hottest summer weather, or when the mercury is 40° below zero or lower. You don't have to empty it or keep it in a warm place in winter, as with ordinary extinguishers. Leave it in an unheated hangar or shed—even on the flying field, if you like. There's nothing to freeze or clog. In the coldest weather you can have about instantly a big volume of liquid under high pressure that will quickly put out any ordinary fire before it gets dangerous.

Every hangar, airport, and airplane factory should have at least one Badger Non-Freeze Engine. It may even be disaster where ordinary fire fighting equipment is useless because of cold.

Badger Non-Freeze Engine can be pushed to fire and operated by one man. A single lever starts the stream. The yearly cost is practically nothing, as depreciation is negligible, and there are no parts to wear out. Recharging cost is minimal.

Badger offers the only approved 40 gallon non-freeze engine. It gives unique year-round fire protection that can not be duplicated elsewhere. Investigate today.

Delay means Danger! Send for details and prices of Non-Freeze Engine—NOW!

an announcement by AMERICAN EAGLE

The flying public looks to American Eagle for progress. American Eagle is regarded in the aeronautical industry as an outstanding example in keeping a step ahead of the pace.

American Eagle aircraft, noteworthy criteria of stability, airworthiness, flyability and ruggedness, day after day, month after month and year after year, have set the pace.

To keep this faith always has been American Eagle's ambition. It always has been the goal of E. E. Porterfield, Jr., American Eagle's president. Each new American Eagle must be better than its predecessor; continually there must be new American Eagles—planes to fill every need of the flying public.

For 1939 American Eagle again strides forward with "something new". Every whim of engineer, production manager, pilot and salesman has been built into the new American Eagles.

Come to St. Louis February 15 to 23, inclusive and let us show you these new American Eagles. They'll be the highlights of the

Brunner Industrial Machine Shop, Outfit Flying Service Station, Buffalo, N. Y.

BRUNNER EQUIPMENT KEEPS THEM IN CONDITION

Compressed air plays an important part in the construction and servicing of aircraft. It saves time and insures better results on such important jobs as engine cleaning, operating pneumatic drills and hardware, tire inflation, greasing, dusting, blowing carbon, testing valves, clearing ships, parts, etc. For the application of lacquer, special aircraft finishes and wing dope, it provides by far the most efficient method.

Brunner Equipment is built to furnish the dependable service which the aircraft industry demands. Models 854 and 868 are recommended for general hangar service. Special spray painting outfits complete with all necessary accessories are also available. Brunner engineers will cooperate in working out your equipment problems. Catalog No. 25 lists the complete Brunner line including spray guns, engine cleaners, blow guns, etc.

Brunner Equipment is sold by aeronautical and automotive jobbers. It is backed by the oldest and largest manufacturer of automotive air compressors in the world.

Reliability and Light Weight Distinguish GENERAL ELECTRIC EQUIPMENT

This Lockheed Delta monoplane was recently built for General Doolittle. It is equipped with the General Electric magnetos and engine. The instrument panel is shown below.

1000 CO. IS THE GENERAL ELECTRIC CO.,
BOSTON, MASS. EVERY SATURDAY AT 9 P.M.,
LISTEN IN A NATION-WIDE R.C. NETWORK

The generating unit in the heart of the magnet compass.

A control knob provides ready access to and the control of the pilot or flyer.

The compass indicator is built in automatic error correction.

The compass controller gives the pilot constant directional control.

THE MAGNETO COMPASS combines reliability and light weight to a degree never before attained in an aircraft instrument of this character. For example, in the generating unit there are no universal joints, a clamped pendulum system insures proper relation with the earth's magnetic field and provides

exceptional stability. Furthermore, directional indications depend upon the position of pole pieces—not the position of the brushes. The weight of the generating unit complete with wind-driven impeller is 5.6 lb. The accessories add about 6 lbs.

THE CARD COMPASS admirably serves the need for an accurate indication of magnetic east. A special vibration-absorbing bracket permits use, ceiling, wall, or panel mounting. Other features include: non-glass lighting; ground-glass lens; luminous dial and lubber line, and adjustable compensation. The weight complete is 2.9 lb.

THE ENGINE TEMPERATURE INDICATOR enables the pilot to read engine temperature direct—regardless of the temperature of the oil supply or cooling liquid. It is accurate and reliable, it requires no battery, it is not connected with the ignition system. The weight complete is 2.2 lb.

THE OIL IMMERSION HEATER should be a part of the equipment of every biplane. It is suitable for connection to any standard electric lighting circuit. Placed in the oil tank of an engine, it heats the oil properly and facilitates a safe, quick start.

RECENT General Electric developments also include built-in, wing-type landing lights and radio-shielding ignition harnesses. For complete information, address the General

Electric Company, Schenectady, N. Y.—manufacturer of lighting equipment, instruments for navigation and flight, engine accessories, and sundry devices for the aeronautics industry.

GENERAL ELECTRIC

Part of the Bellanca flight in Antarctica in the ice of Pt. McMurdo, 1930-31, from photo.

Leading to Bellanca's discovery of Pt. McMurdo with success for the Arctic.

BELLANCA Performance in the Frozen North Again Confirms Bellanca Efficiency

Telegram received by Bellanca Aircraft of Canada, Ltd.—“Congratulations on wonderful combination of Bellanca Pacemaker and Canadiana Wright J-6 engine, both of which functioned perfectly and without complaint over whole mail run from Pt. McMurdo to Akilavik and return despite very severe weather conditions. W. R. Wop May, Commercial Airways, Ltd.”

This airline through the Arctic wilderness has opened a new swift contact with isolated settlements—a step of progress highly significant to Canadian commerce. Passengers, mail and express are flown regularly over the

1,800-mile route with speed and safety, bridging great tracts of almost impassable, heavily-wooded and mountainous country. The Commercial Airways run is one of the most arduous in the world.

Needless to add, the fleet of Bellanca Pacemakers was selected by these veteran operators after the most careful analysis of efficiency and operating economy, followed by tests of several competitive types of aircraft. Such facts as these speak for themselves!

Complete specifications and performance data of the Bellanca Pacemaker on request.

STANDARDIZED HANGARS

New D. W. Young Bureau Hangar at Lethbridge, N. Y., near National Steel Door Curved Track Type.

Truscon has specialized in housing for aeronautical requirements. Truscon Standardized Hangars—furnished in sizes and types for individual requirements—provide clear floor space, thorough fire protection and ample daylight. These permanent hangars can be readily enlarged or re-erected in a new location.

Truscon Steel Hangar Doors open the full width to permit the easy handling of airplanes. They operate easily and are sturdily built to give enduring service. They are furnished in all sizes and may have large glass areas for daylighting. Two types—Straight or Curved Track—are available to meet any hangar requirements.

Write for suggestions, quotations and literature.

It's Pontiac . . .

★—Small white stars indicate Graybar-lighted airports in all parts of the country.

NIGHT after night, the municipal airport at Pontiac stands out on the map—a splash of light against the darkness. It's no task for the night-flier to locate this well-lighted airport. Graybar Airport Lighting has made this task so easy to find . . . so easy to identify . . . so easy and safe to land upon by night as by day.

You'll find many another Graybar Lighted airport from coast to coast. Such wide ex-

perience has made Graybar especially qualified to answer airport lighting questions. How, for instance, must one meet the requirements of the Department of Commerce? What is the best type of beacon? What about audio-power?

For the solution of these and many other lighting problems, Graybar's Airport Lighting Department stands always ready to offer the benefits of its experience to those interested.

Graybar

AIRPORT LIGHTING

An amphibian or flying boat of unusual design and performance. For further information and specifications of the Viking read the page opposite.

A three place plane combining safety and performance—but read the details about the Kittyhawk on the page to the left.

The Viking Amphibian and Flying Boat is the American interpretation of the Schnef F. 8 A. . . a plane that has a record of 6,000,000 miles without a structural accident . . . it is standard equipment in the French Navy—where it receives strenuous use in training pilots and with the fleet at sea.

Built in America by American capital, by American workmen and powered with an American engine . . . the Viking is unusual in design . . . the pusher type propeller forces the stream directly into the tail and elevators giving more positive action on the controls . . . the Viking has a stability, maneuverability and performance which no flying boat in the same price range can equal.

Specifications of the Viking Amphibian and Flying Boat:

High Speed	135 M. P. H.	Duration	4 1/2 hours
Cruising	90 M. P. H.	Length	26 ft. 4 in.
Landing	40 M. P. H.	Height (on wheels)	11 ft. 3 in.
Climb (at Sea level)	600 ft. per min.	Span	42 ft. 3 in.
Service Ceiling	14,000 ft.	Wing Area	448 sq. ft.
Fuel Capacity	50 gals.	Capacity	6 persons
Range	320 miles	Engines—Wright J-4, 2300	225 H. P.

Write to the Viking Flying Boat Company
89 Shelton Ave., New Haven, Conn. or

THE VIKING FLYING BOAT

Experienced pilots have tried to spin the Kittyhawk . . . next have lifted . . . when have succeeded, but even they have been unable to hold it there for more than three or four turns . . . few planes can duplicate that performance.

With a landing speed of 38 miles per hour . . . a wheel tread of 7 ft. 2 in. . . the Kittyhawk is particularly adept at getting in and out of small, rough fields.

Its high factor of safety . . . its performance . . . and low maintenance cost make the Kittyhawk an unusual plane for training and commercial use . . . a plane that even the most critical and experienced pilots will be glad to fly.

Specifications of the Kittyhawk Model B-4

Engine—Kinner K-5	120 h. p.	Weight empty	1120 lbs.
Approved Type Certificate No.	136	Useful load	150 lbs.
Length overall	26 ft. 11 in.	High speed	110 m. p. h.
Height overall	8 ft. 8 in.	Cruising speed	90 m. p. h.
Span both wings	42 ft.	Landing speed	38 m. p. h.
Chord both wings	4 ft. 6 in.	Climb	1200 ft. p. m.
Wing area	223.4 sq. ft.

BALL BEARING Aileron PULLEYS

FORMICA has developed a line of ball bearing aileron pulleys with Fafnir ball bearings which relieve friction, keep in line without wobbling and operate without lubrication difficulties at extreme ranges of temperature.

These bearings will retain lubricant at a temperature of 120 degrees Fahrenheit and the same lubricant will operate efficiently at a temperature of minus 20.

The body of the pulley is the curvass base Bakelite type. Another line of pulleys with bronze bushings is also offered by Formica.

ICE
WARNING
INDICATORS

The Moto Meter Ice Warning Indicator informs the pilot of the atmospheric conditions through which he is flying and enables him to avoid temperatures under which ice might form.

Two atmospheric conditions control ice formation—high humidity and low temperature. High humidity is easily seen as rain, fog, mist, etc. The Moto Meter Ice Warning Indicator keeps the pilot constantly informed of air temperatures.

This instrument is now being used by many of the leading Transport companies.

PRODUCTS

**Be sure
you're right-
then go ahead**

A SOUTHERN city asked our opinion on a rather elaborate airport project under consideration. Much to their satisfaction, we recommended, after careful study, a drastic curtailment of their present program. Our survey had shown that the proposed initial expenditures could be minimally reduced, and at the same time ample provision made for future expansion.

If your city is planning an airport, let A.D.C. specialists make an expert survey of local conditions and a preliminary layout of your requirements. Our recommendations will be unbiased and founded upon wide experience.

Every airport project is a special problem in itself. A.D.C. engineers, executives and pilots coordinate their knowledge to produce just the right job required in each particular case.

STROMBERG

growing with aviation

Years ago when aviation was in the experimental stage Stromberg was experimenting, too, with an aircraft carburetor. One that would be dependable, light. That would supply the proper fuel mixture to the engine at all speeds, in all positions—efficiently and economically.

Such a carburetor was developed. The difficulties of propeller blast and upside down flying were overcome. A dependable, durable, economical carburetor was designed and built.

Years ago when aviation was in the experimental stage Stromberg was experimenting, too, with an aircraft carburetor. One that would be dependable, light. That would supply the proper fuel mixture to the engine at all speeds, in all positions—efficiently and economically.

The aviation world quickly recognized the remarkably fine performance of Stromberg carburetors. With the result that over 90% of American aircraft flying today are Stromberg equipped. And—as aviation grows, and new planes and new engines are developed, invariably builders turn to Stromberg for the solution of their carbureting problems.

STOP FIGHTING COLD WEATHER

Throw away your oil stoves and other motor heaters—Quit fighting frozen oil and cold motors—House your ships and personnel in warm, comfortable hangars.

IDECO Insulated Steel Hangars offer the same protection against cold as 13-in. brick or 20-in. concrete wall construction, yet cost considerably less and retain all of the economies and advantages of steel construction.

An analysis of the heating efficiency made in a comparison between an insulated and uninsulated hangar (60x120x12), located in Michigan, during the winter period revealed a fuel saving in the insulated hangar of 108 tons of coal. 108 tons at \$5.00 per ton is \$540.00.

The insulation feature of IDECO Hangars is a distinctive asset—this is combined with permanence, sectional

interior and exterior views of IDECO Insulated Steel Hangar erected by South Flying Service, War Department, War Relocation Authority.

construction, full fire and rust protection, attractive appearance, full width, easy operating inside opening doors and clear open spans from 40 to 120 ft.

IDECO Hangars offer you the advantages of immediate occupancy, decreased maintenance and insurance costs, complete protection against heat or cold and the release of working capital for other uses.

WRIGHT FLIES
THE DARTMOUTH PROFS!

FOR one whole day Wright's big tri-motor soared over Dartmouth's campus. Every one of its 2500 students, every professor, every college official—and the entire town of Hanover, took keen interest in the flights. For Wright made the trips to demonstrate the practical ease, comfort,

speed, and economy of Aviation. Almost a hundred people went up. But the ones most vitally interested were the Dean and others connected with the Business School. For here they learned at first hand why and how Flying's part in business is growing by leaps and bounds!

WHERE UDYLITE
BEAUTIFIES AND PROTECTS

In The Air With UDYLITE

A mighty transport plane soars through wet clouds; the mail pilot darts below by stealth; a seaplane glides salt water—hardly ever harks to the air. That is why Udylite protection is so popular up there. It is the reason for the Udylite Process guarding our manufacturer's planes which have traveled over eight million miles in the last 28 months.

Precision Products Need this Protection

Whether the product is a swiftly moving plane, a modern automobile, a trim speed boat or precision machinery parts, Udylite is specified as the true protection against rust and corrosion. Submerged in fresh or salt water; subjected to factory steam, cloud moisture or the many other destructive factors, the Udylite Process provides permanent protection, lasting beauty and long, useful life to precision products.

DROP FORGINGS FOR RELIABILITY

On Chambersburg Hammers

Every airplane part that must stand up under the constant grind of repeated service is a vital part. Vital parts such as these illustrated above naturally are drop forgings, and just as naturally were forged on Chambersburg Hammers.

Chambersburg Hammers have been used in the production of forged parts for many of the most important names in the automotive industry since its very beginning . . . And in aviation, the youngest branch of that industry, Chambersburg hammers are again associated with the most important names.

Aerobee View

New Lockheed two-engine monoplane, two-engine great day, built in Los Angeles especially for General Charles A. Lindbergh and equipped with dual controls. Much of the structural structural construction follows the suggestion of the flying school itself. The plane's landing wheel is well ahead 120 miles an hour or so. It has a cruising radius of nearly 3000 miles.

THERE is no substitute for dependability in aviation engines—every unit must bear its share of the loads and stresses with a margin of safety to spare.—Another reason why SSB Ball Bearings predominate in the aviation engine field.

SSB construction with its maximum number of largest possible balls, all of which are hot-forged from Molybdenum steel, gives that added factor of safety which is so essential.

Specify SSB Ball Bearings for longer life and increased efficiency.

3 pioneers pass another milestone of dependable service

The passing of 1929 marked the close of another year of dependable service by the air mail . . . that pioneer of commercial aviation.

Likewise, 1929 marked the completion of a year of dependable service by two other pioneers in the aviation industry . . . Stanolind Aviation Gasoline, Stanolind Aero Oil. Early in the history of commercial aviation these two products began to contribute their share to the success of flying. No more convincing proof of the dependability with which they perform can be found than in the record they have made . . . many thousands of flying hours with never an engine failure traceable to any fault in either of these products.

Today Stanolind Aviation Gasoline and Aero Oils are better than ever. Constant research work keeps them up to date to meet the ever changing requirements for aviation fuel and lubrication.

Stanolind Aviation Gasoline and Aero Oils are well known at midwestern airports and preferred by the majority of pilots. These men know that they can rely on Stanolind Aero Products.

THE COMET

"direct action valve gear"—FOR SAFETY

Sketch showing valve actuating mechanism of typical cable-actuated engine and Comet single-rocker-arm engine. Arrows show direction of force applied to rocker arm compared with direction of motion desired.

WHEN you lift a load you get directly under or over it. You don't apply force at an angle. That would waste effort by pushing or pulling to one side. That's where the Comet valve gear has another advantage.

Why?

The Comet valve gear applies its effort in the direction of the movement desired. The force is not wasted in trying to twist the rocker arm to one side or in trying to tip the cylinder off its base. This reduces back lash and weight, and as a result, greatly reduces wear in the bearings. Comet valve clearance adjustments need be made only at approximately 50 hour intervals—5,000 miles of flying—your motor car will hardly do better.

Then, too, the entire Comet valve mechanism—trippet, pushpull rod, and rocker arm—is positively moved in both directions by the cam. Other engines depend on the valve spring to return the system to neutral position. Thus the Comet valve springs are much lighter and carry less load, since they serve only to seat the valve itself. Less load—less wear—less maintenance—less expense.

And, above all, one valvetraining system does the work of two. Another reason why owners of Comet engines are—

A Comet engine is on exhibit at Booths 43 and 44 Building "B", International Aircraft Exposition, St. Louis.

at ease in the air
COMET ENGINE CORPORATION

Speed Stability Economy

IT'S the rare combination of all three of these qualities in one airplane that makes the Davis D-1 Monoplane so out of the ordinary.

Here's a cruising speed of 85 miles per hour—with a gasoline consumption of only 4½ gallons per hour. Top speed of 101! Here's the stability of larger and heavier planes, achieved in the D-1 by the unique wing design characteristic of all Davis Monoplanes. And with it, you'll find an eager response to controls rivaling a parasol plane.

Here's the exceptional acrobatics and

PERFORMANCE (Actual)

Type	D-1—La Jolla 01	D-1—Kansas 10
Service Ceiling	10,000 feet	14,000 feet
High Speed	100 M. P. H.	121 M. P. H.
Landing Speed	38 M. P. H.	40 M. P. H.
Cruising Speed	85 M. P. H.	100 M. P. H.

\$100,000 SAFETY PRIZE WINNER

Controlled with the aid of FAFNIRS

SAFETY to a degree that makes a plane practically "foolproof" was the basis of the Guggenheim award to the Curtiss Tanager. Slotted wings and the so-called "Roasting" aileron were outstanding features, but every detail was designed to contribute its share towards safety.

The advanced Control system which triumphed in this competition presupposed the use of ball bearings. Control pulleys, for instance, were mounted on Fafnirs to give that sensitive reliability essential in the more difficult tests.

Curtiss, appreciating the value of the Ball Bearing design, uses Fafnirs in other applications, in other ships, other models. Fafnir Ball Bearings are made for every aircraft application. Send for special data sheets.

Chicago Milwaukee Detroit Evansville Cleveland Philadelphia

FAFNIR BALL BEARINGS

THE MOST COMPLETE LINE OF BALL BEARINGS IN AMERICA

Specializing

SPECIALIZING in the manufacture of tanks and cowlings and motor parts and the volume of our business permits a greater degree of accuracy and finer workmanship, at a price per unit below the production costs on like products manufactured by individual aircraft producers.

Here you will find a modern plant well equipped to serve you with an engineering staff composed of specialists working on airplane parts strictly and whose reputation for doing good work places them among the leading authorities in their particular phase of aircraft design and manufacture.

There is no other factory substantiated for experience and equipment in designing and manufacturing tanks and cowlings. Like "flying boats" you either have them or you don't.

in Parts...

If you believe that the design and manufacture of tanks and cowlings and smaller parts is just as vital to efficiency and structural strength as the principal components which lend themselves to ready inspection, you will find our company your logical source of supply.

We invite you to visit our plant while attending the St. Louis Air Show, or advise us of your requirements and we will be pleased to serve you.

STUART AERO PRODUCTS, INC.
Thirteenth and Roger ST. LOUIS, MO.

Your safeguard in airplane engine building or replacement is a ready one whether these "light things" are safe before they are installed.

All Stuart parts are true in pattern, are true in quality, and cheaply depend able.
